## 'Plumbogummite' from Roughten Gill, Cumberland

## By E. B. Förtsch

Department of Geology, University of Pretoria, R.S.A.

[Taken as read 2 November 1967]

Summary. X-ray, infra-red, and optical studies suggest that the bluish-grey crust (previously described as plumbogummite) on arsenian pyromorphite from Roughten Gill, Cumberland, is a carbonate-bearing mix-crystal of plumbogummite, hinsdalite, and hidalgoite with a 7.018 Å, c 16.784 Å;  $a_{7h}$  6.907, a 61° 3′;  $\omega$  1.680,  $\epsilon$  1.698.

**D**URING a reinvestigation of the pyromorphite group of minerals, (Förtsch, 1964), a sample (Fö 63) from Roughten Gill, Cumberland, was encountered, which is zoned, ranging from an arsenian pyromorphite (*circa* 12 mol. % mimetite) to a campylite (*circa* 50 mol. % mimetite), and is encrusted by a bluish-grey mineral. This sample was obtained from the Mineralogical Museum, University of Bonn, Germany. Although the bluish-grey mineral was labelled as a silicate of zinc (Bonn 335/9, 775), its X-ray powder pattern is similar to that of hidalgoite (ASTM 6-0380, Smith *et al.*, 1953); but their *d*-values differ noticeably. A similarity in structure could, nevertheless, be assumed.

Miers (1897, 1900) describes material from Roughten Gill that corresponds to the material investigated: '... This beautiful blue substance occurs as a crust which generally lies directly upon the vein quartz, and usually has crystals of pyromorphite dispersed upon it. The pyromorphite crystals are sometimes quite fresh, but are often surrounded by a zone of hitchcockite [= plumbogummite], and on some specimens are only represented by hollow pseudomorphs consisting entirely of hitchcockite; ...' Hartley (1900) published chemical analyses of the blue mineral and of plumbogummite from various localities, and Miers (1900) gave optical observations on the minerals analysed by Hartley. The close relationship of the minerals hamlinite [goyazite], florencite, plumbogummite, beudandite, and svanbergite is discussed by Prior (1900).

Plumbogummite from Cherokee, Georgia, U.S.A., is listed as No. 2-0683 in the ASTM data file and the accompanying refractive indices are taken from Winchell (1951, p. 229). Owing to the imperfect *d*-values

and the absence of lattice constants as well as Miller indices, new d-spacings (table I) and lattice constants are now presented for the Roughten Gill mineral.

X-ray powder data were obtained with a Guinier-type AEG-camera developed by Jagodzinski, using monochromatic Cu- $K\alpha$  radiation and silicon as an internal standard. The pattern (table I) could be indexed on the assumption that the mineral has a structure similar to that of

FIG. 1. X-ray powder photograph of 'plumbogummite' Fö 63, Roughten Gill, Cumberland, taken in Guinier camera with Cu-K $\alpha$  radiation. 4 $\theta$ -range 30° to 125° (actual size). Si-standard lines are marked with dots, Vaseline (v), quartz (q), unidentified (x).

hidalgoite. Reflections were present only when -h+k+l = 3n, indicating a rhombohedral space-group. The unit cell dimensions are:  $a \ 7.018 \pm 0.002$  Å,  $c \ 16.784 \pm 0.003$  Å,  $c/a \ 2.3915$ ;  $a_{rh} \ 6.907 \pm 0.002$  Å,  $\alpha \ 61^{\circ} \ 3' \pm 2'$ . Calculated  $\sin^2\theta$  from these parameters are in good agreement with the measurements.

The *d*-spacings of a hinsdalite from Colettes (Nicolas and de Rosen, 1963) are included in table I for comparison; there is a good agreement between the *d*-values of these two minerals and it therefore seems as though one of them, or possibly both, were incorrectly identified. The *d*-values of hinsdalite from the type locality, Lake City, Hinsdale County, Colorado, listed by Nicolas and de Rosen (1963) and on the ASTM card No. 14–185 respectively, differ slightly from each other as well as from those of hinsdalite from Colettes and 'plumbogummite' from Roughten Gill.

The X-ray powder diffraction photograph (fig. 1) shows, besides the Si (internal standard), Vaseline (sample preparation) and quartz lines, some very weak lines that could not be accounted for. If, however, the a constant is trebled, possible indices are obtained for these lines:

hkil	$51\overline{6}1$	$34\overline{7}2$	$31\overline{4}8$	$11\overline{2}9$	$2.10.\overline{12}.1$	$9.2.\overline{1}\overline{1}.7$
$\sin^2\theta_{obs.}$	0.05771	0.07450	0.15740	0.17661	0.22400	0.28710
$\sin^2\theta_{calc.}$	0.05752	0.07457	0.15825	0.17624	0.22375	0.28748

The only value that lies slightly outside the experimental error is that of  $31\overline{48}$ . Unfortunately, the proposed trebling of the *a* value could not be verified by single crystal photographs.

TABLE I. X-ray powder data for 'plumbogummite' (Fö 63) from Roughten Gill, Cumberland. Guinier-camera, Cu- $K\alpha$  radiation ( $\lambda$  1.5418 Å), a 7.018 $\pm$ 0.002 Å, c 16.784 $\pm$ 0.003 Å, c/a 2.3915, space group  $R\overline{3}m$  or R3m, intensities: visual estimate, B = broad; all permitted values of  $\sin^2\theta$  are shown up to 0.37261. For comparison d-values of hinsdalite from Colettes (Nicolas and de Rosen, 1963, p. 382).

TABLE I—continued

 \* quarts.
 † indices not conforming to rhombohedral criteria.
 ‡ Vaseline.

 § unidentified lines (see text for trebling of a constant).
 || Si-standard.

 ¶ camouflaged by Si.
 \*\* plus quartz.

Single crystal rotation photographs, taken with the axis of the fibre bundle as the rotation axis, resemble a powder photograph with distinct shape orientation due to the fact that the fibres are very fine and subparallel (fig. 2). If the stronger reflections are associated with the corresponding layer lines, their hkl's agree with those obtained from the powder pattern; the fibre axes correspond to the *c*-axis.

Optical study. The refractive indices measured in Na-light are intermediate between those of hidalgoite (Smith *et al.*, p. 1219) and hinsdalite from Hinsdale County (Dana, 1951, p. 1004), and much higher than those of plumbogummite from Canton Mine, Georgia (Dana, 1951, p. 831):

hidalgoite mean	n 1.705 - 1.713	
'plumbogummite'	$1.680 \pm 0.002$	$\epsilon 1.698 \pm 0.002$
hinsdalite	1.670	1.689
plumbogummite	$1.653 {\pm} 0.01$	$1.675 {\pm} 0.01$

A thin section parallel to (0001) of the zoned arsenian pyromorphite

host shows the 'plumbogummite' to have grown in rhythmic shells. The sub-parallel orientation of the fibres as well as their orientated relationship to the host can be seen under crossed nicols (fig. 2).

FIG. 2. Zoned arsenian pyromorphite (dark) with rhythmic layers of 'plumbogummite' (light). Fibre axes of 'plumbogummite' (dark in the east and west segments) are parallel to the thin section. Crossed nicols,  $\times 37$ . (Actual width of crystal is 1 mm.)

Chemical data. If the chemical analysis of plumbogummite from Roughten Gill by Hartley (1900) is compared with the theoretical composition as calculated from the formula  $PbAl_3H[(OH)_6/(PO_4)_2]$ , a relative deficiency of  $P_2O_5$  and PbO and a surplus of  $Al_2O_3$  and  $H_2O$  are observed (table II). Furthermore,  $CO_2$ is not accounted for.

When recalculating the chemical analysis of Hartley (table II) the  $CO_2$ was not regarded as an impurity, as no carbonates were detected in the Xray powder pattern, and C therefore is believed to substitute for P. It is suggested that the  $CO_3$  ions are accompanied by an equivalent number of OH in the replacement of  $PO_4$ . Not

only is the charge balance maintained, but the tetrahedral coordination for P-position atoms is also preserved. Part of the surplus Al is also assigned to tetrahedral positions with twice the number of OH accompanying them. In order to maintain the charge balance, still more OH has to take the place of O, and the remaining OH is converted to  $H_2O$ . This type of substitution does, however, produce a decrease in total charges in the structure. Other possibilities would be to retain eight oxygen in the formula and to balance the charges with hydrogen ions, or to bring in only the equivalent amount of OH for C and Al, and then balance with hydrogen ions (table II).

Infra-red examination. Because very little material of the 'plumbogummite' was available, only an infra-red absorption spectrum was recorded. Hidalgoite, the As-analogue of hinsdalite, was used for comparison. A sample (U.S. Nat. Museum No. 112728) was kindly supplied through the courtesy of Mr. R. L. Smith. The infra-red absorption spectra were recorded in the 4000 to 670 cm<sup>-1</sup> (2·5–15  $\mu$ ) region on a Perkin-Elmer 221 Infrared Spectrometer equipped with NaCl prism, at sample concentrations of 1·2 mg in 11-mm diameter KBr discs.

TABLE II. Chemical composition of the 'plumbogummite' from Roughten Gill compared with the theoretical composition of plumbogummite; with possible interpretations of the analysis.

	1	$^{2}$		1a
PbO	37.03	38.44	Pb	0.93

1. 'Plumbogummite', Roughten Gill, anal. E. G. J. Hartley, 1900.

2. Theoretical composition of plumbogummite, PbAl<sub>3</sub>H(PO<sub>4</sub>)<sub>2</sub>(OH)<sub>6</sub>.

1a. Atomic ratios calculated for 6 cations (Pb, Al, P, and C).

 $\begin{array}{l} Possible \ structural \ formulae \ (see \ text) \\ Pb_{0\cdot 93}Al_{3\cdot 07}[(P_{1\cdot 48}C_{0\cdot 40}Al_{0\cdot 12})O_{6\cdot 43}(OH)_{1\cdot 57}/(OH)_{6}].0\cdot 38H_{2}O \\ or \\ Pb_{0\cdot 93}Al_{3\cdot 07}H_{1\cdot 57}[(P_{1\cdot 48}C_{0\cdot 40}Al_{0\cdot 12})O_{8}(OH)_{6}].0\cdot 38H_{2}O \\ or \end{array}$ 

 $\mathrm{Pb}_{0\cdot 93}\mathrm{Al}_{3\cdot 07}\mathrm{H}_{0\cdot 93}[(\mathrm{P}_{1\cdot 48}\mathrm{C}_{0\cdot 40}\mathrm{Al}_{0\cdot 12})\mathrm{O}_{7\cdot 36}(\mathrm{OH})_{0\cdot 64}/(\mathrm{OH})_{6}].0\cdot 38\mathrm{H}_{2}\mathrm{O}$ 

The absorption spectra obtained are reproduced in fig. 3. The wavenumbers of the bands are: for 'plumbogummite' Fö 63, 3413, 3125, 2358, 1636, 1470, 1412, 1182, 1101, 1030, 866, 797, 778, and 689 cm<sup>-1</sup>, and for hidalgoite U.S.N.M. 112728, 3448, 3067, 2358, 1633, 1210, 1079, 1015, 967, and 860 cm<sup>-1</sup>. The original spectra are filed at the Physikalisch Chemischen Institut, Freiburg University, Freiburg im Breisgau, Germany, nos. 16459 and 16458 respectively. Using Moenke's (1962) published spectra cards it was possible to identify the bands resulting from OH, SO<sub>4</sub>, and AsO<sub>4</sub> in the case of hidalgoite. 'Plumbogummite', on the other hand, gave a spectrum with more bands although, according to its ideal formula, it should have fewer. Owing to superposition of bands, the transmission is lower over a wide range of the spectrum. Bands due to hydroxyl and water are clearly visible in the  $3 \mu$  and  $6 \mu$ regions. The double band in the  $7 \mu$  region is allotted to CO<sub>3</sub>. It is interesting to note that Gulbrandsen et al. (1966) also found a double band in the 7  $\mu$  region in a carbonate-bearing apatite. They attribute it to the different environment of the CO3 ion in apatite compared with calcite where only one band is present. Similar reasons can be advanced for the double band in 'plumbogummite' because cerussite, too, exhibits only one band (Adler and Kerr, 1963, p. 127). This seems to be in accordance with the structural formula as calculated from Hartley's analysis.

It is suggested that a double band due to  $SO_4$  is partly superimposed on the  $PO_4$  doublet in the 8 to 11  $\mu$  region. The band at 866 cm<sup>-1</sup> seems to indicate  $AsO_4$ . Although the material was hand-picked under a binocular microscope, part of the  $AsO_4$  could be due to very minute campylite crystals, which are dispersed on the 'plumbogummite'.

FIG. 3. Infra-red absorption spectra of hidalgoite (U.S. Nat. Museum, No. 112728) and 'plumbogummite' (Fö 63), from Roughten Gill, Cumberland (bottom).

Another absorption band  $(v_3)$  of the CO<sub>3</sub> ion, however, falls in the same region, and it is therefore difficult to evaluate how much AsO<sub>4</sub>, if any, contributed to that absorption band. The bands at 797 cm<sup>-1</sup> and 778 cm<sup>-1</sup> correspond to quartz, the presence of which is indicated by the X-ray powder photograph, while the small band at 689 cm<sup>-1</sup> could be due to the  $v_4$  mode of the CO<sub>3</sub> ion.

Discussion. The d-values of hinsdalite (Nicolas and de Rosen, 1956, p. 382) are in good agreement with those of the 'plumbogummite' of the present investigation (table I). Regarding the composition of this hinsdalite only qualitative chemical results are given (p. 383), namely P, Pb, Al present, and  $SO_4$ -reaction positive, and its chemical formula is thus only tentative.

If the components  $PO_4$ ,  $SO_4$ ,  $CO_3$ , and  $AsO_4$ , as suggested by the infrared spectrum, are in fact present, then the 'plumbogummite' under discussion would be a carbonate-bearing mix-crystal of hinsdalite,

## 'PLUMBOGUMMITE'

plumbogummite, and hidalgoite. Such a composition is also in closer agreement with the measured refractive indices. Unfortunately, Miers (1900) did not determine the refractive indices of the sample analysed by Hartley (1900). Regarding the hinsdalite from Colettes, Nicolas and de Rosen only mention that it is uniaxial positive with first-order yellow interference colours (presumably thin section-thickness).

A mix-crystal containing hidalgoite and hinsdalite in equal proportions would imply that the atomic ratio (As+P):S = 1:1; a mineral of such a composition would have higher refractive indices than the mineral under discussion. Although the exact proportions of P, S, and As are not known, it can be deduced from the infra-red absorption spectrum that PO<sub>4</sub> is much in excess of AsO<sub>4</sub>. If it is kept in mind that the v<sub>2</sub> mode of the CO<sub>3</sub> ion is partly superimposed on the AsO<sub>4</sub> band in the 11 to 12  $\mu$  region, then the possibility of a carbonate-bearing mix-crystal of plumbogummite and hinsdalite is not ruled out.

Acknowledgements. The writer wishes to express gratitude to Prof. H. Wondratschek for his support and supervision in the Department of Mineralogy at Freiburg University, where most of the research was carried out. Professor R. Mecke, director of the Physikalisch-Chemische Institut at Freiburg University generously permitted the use of an infrared spectrometer. The award of a DAAD exchange-bursary is gratefully acknowledged. The Deutsche Forschungsgemeinschaft made the investigation possible by providing essential instruments. Appreciation is expressed to Dr. E. A. Retief for critically reading the manuscript.
