For domes: If $\mathrm{x}=0, \tan \varphi=0, \varphi=0 ; \tan \rho=\mathrm{q} \mathrm{q}_{0}$.

$$
\text { If } \mathrm{y}=0, \tan \varphi=\infty, \varphi=90^{\circ} ; \tan \rho=\mathrm{pp}_{0} .
$$

For prisms:

$$
\frac{p}{q} \infty, \tan \varphi=\frac{p p_{0}}{q q_{0}} ; \tan \rho=\infty, \rho=90^{\circ} .
$$

## ILLUSTRATION OF THE ORTHORHOMBIC SYSTEM. MEASUREMENTS AND CALCULATIONS ON HIGGINSITE

CHARLES PALACHE<br>Harvard University

As an illustration of the application of the formulas given in the preceding article, the following discussion of a crystal of the new mineral higginsite, described above, may well serve. The measurements of one crystal are given in full in Table 1, the form of calculation being that used thruout in Goldschmidt's work. In this table, columns 1, 2, 5, and 6 contain the record of actual observation on the goniometer. The numbers of col. 1 are those used to mark the faces in the note-book sketch of the crystal; the letters of col. 2 stand for good, fair and poor, depending on the quality of the reflected signals; col. 5 contains the angles read on the vertical circle, V, col. 6 those on the horizontal circle, H , of the goniometer.

These angles were plotted in gnomonic projection yielding a diagram similar to figure 33. The next step was the choice of the unit form. Either of the pyramids, o and p, might have been taken for this and its coördinates would then have been the elements, $p_{0}$ and $q_{0}$. The choice fell upon o because this form is more prominently developed on the crystals; the zonal relations with other forms are at least as good; and its selection brings to expression the isomorphism of the new species with descloizite, as will be shown below.
The unit form chosen, the Goldschmidt symbols could be read at once from the projection; they are entered in col. 3. The letters of col. 4 follow the usage for the mineral descloizite.

Determination of the value $\mathrm{v}_{0}$ was next in order. The projection showed that the face 1 will have $\varphi=0$, and therefore $\mathrm{v}_{0}$ would be close to $77^{\circ} 28^{\prime}$, the V reading of face 1 . Each of the pairs of faces: 2 and $3 ; 4$ and $5 ; 8$ and 9 ; are symmetrically dis-

Fig. 33
posed to 1 , and the half-sums of the $V$ readings of each pair gave independent values for $v_{0}$. Faces 6 and 7 should be $90^{\circ}$ from face 1 in $\varphi$, and the prism faces also yielded, either directly or by taking the half-sum of symmetrical readings, other values of $\mathrm{v}_{0}$. The average of all is $77^{\circ} 29^{\prime}$ which, subtracted from each angle in col. 5 , gives the values of $\varphi$ entered in col. 7 .
Col. 8 contains the values of $\rho$ obtained from col. 6 by subtracting each from $h_{0}=260^{\circ}$, a constant for the instrument.

The calculation of $p_{0}$ and $q_{0}$ followed. In col. 9 was written first, $\lg \tan \rho$ for each face (except prisms); then $\lg \sin \varphi$ and $\lg \cos \varphi$ respectively above and below the first. Col. 10 contains the sums of these logarithms, above the upper two, below the lower two, the logarithms respectively of x and y . This addition proceeds most rapidly if done beginning at the left hand side of the numbers to be added, the sum being then written in col. 10 in order from left to right, a trick of addition (or subtraction)

Table 1, on following page and half of page 162, gives the measurements on the higginsite and the calculations therefrom.

soon learned with a little practice. All the logarithms of col. 10 having been obtained, the numbers corresponding to each were found from the table, and entered in col. 11 opposite each. The upper number of each horizontal line in col. 11 is a value of $\mathrm{x}=\mathrm{pp}_{0}$; the lower a value of $y=q q_{0} . \quad p$ and $q$ having been determined graphically (s y mbol, col. 3) the numbers of col. 11 yielded a series of values for $p_{0}\left(1 / 2 p_{0}\right.$ in col. 12) and $q_{0}$ (col. 13) the average of which gave the elements of the crystal. The prisms yielded the ratio of $p_{0}$ to $q_{0}$ by a simple calculation as shown. The result of the calculation of this crystal were as follows:
$\mathrm{p}_{0}=1.2654 ; \mathrm{q}_{0}=0.7919 ;$
$\frac{p_{0}}{q_{0}}=1.597$ (from prisms $\frac{p_{0}}{q_{0}}=1.599$ ).
Asimilar calculation may be made for each crystal measured and the results averaged. Possibly a simpler method is to average the angles for each form, make one calculation from these angles, and, weighting the resulting element values according to the number and quality of the readings for each form, find a final average. Table 2 shows the observed forms and angles (averaged) measured on eight crystals of higginsite together with the range of variation of each angle. The values of the elements $p_{0}$ and $q_{0}$ there given are the basis for the calculation of the $\varphi$ and $\rho$ angles of the same table. Table 3 shows the meth-
od of this calculation. The columns are numbered and the nature of the content of each is indicated by the heading. The lowest group of figures in each heading indicates the operation by which the values of the column were obtained. For example in col. 3, $(1+\mathrm{lg} . \mathrm{p})$ means that $\mathrm{lg} . \mathrm{p}$ is added to each logarithm of col. 1 ; in col. 5, (3-4) means that the logarithm of col. 4 is to be subtracted from that of col. 3; in col. $9(3-6=4-7)$ means that the result of subtracting each logarithm of col. 6 from that of col. 3 should equal the result of subtracting each logarithm of col. 7 from that of col. 4. Incidentally this identity is a check on the calculation of each set of angles. After the values of $\mathrm{lg} . \tan \varphi$ are obtained in col. 5 , the angle is found from the table, entered in col. 8 and at the same time the lg . sin and lg . cos entered in cols. 6 and 7. $\rho$ is obtained from Ig. $\tan \rho$ of col. 9 .

Each operation is thus a horizontal addition or subtraction or the result of adding a common value to a vertical series of numbers. All operations are supposed to be done mentally or with the aid of a slip of paper on which a commonly used value may be written. With comparatively little practice they become very easy and rapid.
In the Introduction to Goldschmidt's Winkeltabellen will be found forms similar to this for the calculation of crystals of each system. It was in this way that the enormous labor of calculating all the angles contained in that work was accomplished.

LISTS OF THE ORTHORHOMBIC MINERALS INCLUDED IN GOLDSCHMIDT'S WINKELTABELLEN. Edgar T. Wherry. Washington, D. C.-As the prism zone is on the whole most characteristic of orthorhombic crystals, it has seemed desirable to arrange the minerals of this system in the order of increasing values of axis $a$.

Orthorhombic Minerals
