# Reinerite, $\mathrm{Zn}_{3}\left(\mathrm{AsO}_{3}\right)_{2}$ : an arsenite with a novel type of Zn -tetrahedral double chain ${ }^{1}$ 

Subrata Ghose, Paul Boving, William A. LaChapelle and Che'ng Wan<br>Department of Geological Sciences, University of Washington<br>Seattle, Washington 98195

#### Abstract

Reinerite, $\mathrm{Zn}_{3}\left(\mathrm{AsO}_{3}\right)_{2}$ from Tsumeb, S. W. Africa, is orthorhombic, with cell dimensions $a$ $=6.092(2), b=14.407(2), c=7.811(1) \mathrm{A}$, space group Pbam and $Z=4$. The crystal structure has been determined by the symbolic addition method and difference Fourier synthesis and refined by the method of least squares to an $R$ factor of 0.051 based on 1289 reflections, measured on an automatic single-crystal diffractometer. The standard deviation in $\mathrm{Zn}-\mathrm{O}$ and As- O bond lengths is 0.003 and 0.004 A and in $\mathrm{O}-\mathrm{Zn}-\mathrm{O}$ and $\mathrm{O}-\mathrm{As}-\mathrm{O}$ angles $0.02^{\circ}$.

The structure of reinerite contains a new type of Zn -tetrahedral double chain, $\left[\mathrm{Zn}_{4} \mathrm{O}_{10}\right]_{\infty}$, with two-tetrahedral repeat and four-membered rings; these double chains are cross-linked into a three-dimensional framework through corner-sharing of a new type of edge-sharing Zn tetrahedral dimers and two types of trigonal pyramidal arsenite groups. The average $\mathrm{Zn}-\mathrm{O}$ bond distances within the two independent $\mathrm{Zn}-\mathrm{O}$ tetrahedra are 1.958 and 1.964 A . Both the arsenite groups have the point symmetry $m$, with average As-O bond distances 1.776 and 1.771 A and average $\mathrm{O}-\mathrm{As}-\mathrm{O}$ bond angles 98.4 and $96.8^{\circ}$.

## Introduction

In the course of our investigation of the stereochemistry of copper and zinc (Ghose and Wan, 1974; Ghose et al., 1974), we have now determined the crystal structure of reinerite, $\mathrm{Zn}_{3}\left(\mathrm{AsO}_{3}\right)_{2}$, from Tsumeb, S.W. Africa. At Tsumeb, it occurs at a depth of 800 m in a second oxidation zone of the lead-zinccopper deposit, in association with smithsonite, hydrozincite, hemimorphite, willemite, adamite, and olivenite (Geier and Weber, 1958). In addition to the configuration of the arsenite group, the crystal structure of reinerite turned out to be of considerable interest, because it contains a new type of double chain consisting of corner-sharing $\mathrm{ZnO}_{4}$ tetrahedra, reminiscent of the amphibole-type tetrahedral silicate double chains, and an edge-sharing Zn -tetrahedral dimer.

## Experimental

Reinerite was reported to be orthorhombic with possible space group Pmma by Geier and Weber (1958). Precession photographs of a reinerite crystal from Tsumeb revealed extinction conditions as $0 \mathrm{kl}, k$

[^0]$=2 n$ and $h 0 l, h=2 n$ present. Of the two possible space groups, Pbam and Pba2, the first proved to be correct on the basis of an $N(z)$-test of the measured X-ray diffraction intensities.

A single crystal of light blue transparent reinerite was checked for crystal perfection through a transmission Laue photograph and then ground to a sphere of diameter $0.225(2) \mathrm{mm}$. The single-crystal sphere was mounted on the syntex $\mathrm{P} \overline{1}$ single-crystal diffractometer, and the unit-cell dimensions were refined by the least-squares method based on 15 reflections with measured $2 \theta$ values between 35 and $45^{\circ}$, using $\mathrm{Mo} K \alpha$ radiation. The cell dimensions (Table 1) are in good agreement with those determined by Geier and Weber. All ( $h k l$ ) reflections within $2 \theta=$ $65^{\circ}$ were measured on the diffractometer by the $2 \theta-\theta$ scan method, using MoK $\alpha$ radiation monochromatized by reflection from a graphite "single" crystal, and scintillation counter. A variable scan rate was used, the minimum being $1^{\circ} / \min (50 \mathrm{kV}, 15$ mA ). Out of a total of 1289 reflections, 239 were less than $3 \sigma(I)$, where $\sigma(I)$ is the standard deviation of the measured intensity as determined by the counting statistics. All the intensities were corrected for Lorentz, polarization, and absorption factors.

Space Group: Pbom

## Determination and refinement of the structure

A three-dimensional Patterson synthesis was computed. However, due to the interaction of four heavy atoms, the interpretation of the Patterson map proved to be difficult. The four heavy-atom positions were determined directly by the symbolic addition method (Karle and Karle, 1966) using the computer program MULTAN (Germain et al., 1971). The E values for all reflections were calculated. The signs of the following three reflections with large E values were chosen to define the origin:

| $h$ | $k$ | $l$ | E | Sign |
| :---: | :---: | :---: | :---: | :---: |
| 1 | 9 | 2 | 2.94 | + |
| 3 | 6 | 2 | 2.75 | + |
| 1 | 7 | 7 | 2.41 | - |

In addition, the application of the $\Sigma_{1}$ relationship indicated the signs of two more reflections $(0,0,10)$ and $(18,2,0)$ with E values 1.90 and 1.65 respectively to be,++ . The following three reflections were assigned symbols:

| $h$ | $k$ | $l$ | E | $\operatorname{Sign}$ |
| :--- | :--- | :--- | :---: | :---: |
| 0 | 16 | 5 | 3.24 | $e$ |
| 1 | 11 | 5 | 2.54 | $f$ |
| 4 | 1 | 2 | 2.53 | $g$ |

Signs and symbols of 153 reflections with $E>1.60$ were determined. Out of the eight possible E maps, one showed the correct structure in terms of the heavy atoms, namely 2 Zn and 2 As . The symbols e,f, $g$ turned out to be,,-+- . A structure-factor calculation with the heavy atoms only yielded an $R$ factor of 0.27 .

The oxygen positions were determined from a three-dimensional difference Fourier synthesis. The $R$ factor at this stage was 0.21 . The structure was refined by the method of least squares using the program RFINE (Finger, 1969), first using isotropic and then anisotropic temperature factors for all atoms. The scattering factors were taken from Cromer and Mann (1968), corrected for anomalous dispersion (Cromer and Liberman, 1970). The observed structure factors $F_{0}$ 's were weighted by $1 / \sigma^{2}\left(F_{0}\right)$, where $\sigma\left(F_{0}\right)$ is the standard deviation of $F_{0}$. A few strong low-angle reflections (e.g. 004, 121) were strongly affected by extinction. These reflections with $\Delta F>$ 10.0 were excluded from the refinement. The final $R$ factor is 0.051 for all (1289) reflections and 0.046 excluding 18 reflections affected by extinction. The shift/error at this stage is 0.00 . The atomic positional and thermal parameters are listed in Table 2 and a list of observed and calculated structure factors in Table 3. ${ }^{2}$ The standard deviations in bond lengths and an-

[^2]gles as well as in thermal ellipsoids were calculated using the ERROR program (Finger, personal communication, 1972). The bond lengths and angles are listed in Table 4, and the dimensions of the thermal ellipsoids in Table 5. The average standard deviation in $\mathrm{Zn}-\mathrm{O}$ and As-O bond lengths are 0.003 and 0.004 A , respectively, and in $\mathrm{O}-\mathrm{Zn}-\mathrm{O}$ and $\mathrm{O}-\mathrm{As}-\mathrm{O}$ angles $0.02^{\circ}$.

## Description of the structure

The crystal structure of reinerite is a three-dimensional framework, consisting of three distinct structural components: (a) dimers of edge-sharing

$\mathrm{Zn}(1) \mathrm{O}_{4}$ tetrahedra; (b) tetrahedral double chains, made up of corner-sharing $\mathrm{Zn}(2) \mathrm{O}_{4}$ tetrahedra; and (c) two isolated trigonal-pyramidal arsenite groups, $\mathrm{As}(1) \mathrm{O}_{3}$ and $\mathrm{As}(2) \mathrm{O}_{3}$.
(a) Tetrahedral edge-sharing dimer, $\left[\mathrm{Zn}_{2} \mathrm{O}_{6}\right]^{8-}$

Two $\mathrm{Zn}(1) \mathrm{O}_{4}$ tetrahedra share the $\mathrm{O}(1)-\mathrm{O}\left(1^{\prime}\right)$ edge across a mirror plane, forming a $\left[\mathrm{Zn}_{2} \mathrm{O}_{6}\right]^{8-}$ dimer (Figs. 1 and 2). This dimer is apparently of a new type. Because of the edge-sharing, the $\mathrm{Zn}(1) \mathrm{O}_{4}$ tetrahedron (av. $\mathrm{Zn}-\mathrm{O}$ distance 1.958 A ) is highly distorted; the shared edge, $\mathrm{O}(1)-\mathrm{O}\left(1^{\prime}\right)(2.709 \mathrm{~A})$ is much shorter than the average tetrahedral edge distance (3.173A) , and the $\mathrm{O}(1)-\mathrm{Zn}(1)-\mathrm{O}\left(1^{\prime}\right)$ angle $\left(86.1^{\circ}\right)$ is much smaller than the average tetrahedral angle. The $\mathrm{Zn}(1)-\mathrm{Zn}\left(1^{\prime}\right)$ distance within the dimer is 2.897 A . Although a similar edge-sharing tetrahedral silicate dimer would be very unlikely, a topologically comparable $\left[\mathrm{Be}_{2} \mathrm{O}_{6}\right]^{8-}$ dimer has been found in epididymite, $\mathrm{HNaBeSi}_{3} \mathrm{O}_{8}$ (Robinson and Fang, 1970).

## (b) Tetrahedral double chains, $\left[\mathrm{Zn}_{4} \mathrm{O}_{10}\right]_{\infty}^{12-}$

A tetrahedral single chain running parallel to the $a$ axis is formed by $\mathrm{Zn}(2)$-tetrahedra sharing the oxygen corner, $\mathrm{O}(3)$. Two such single chains across a mirror plane share corners, to form double chains (Figs. 2, 3 and 4a). In Liebau's (1972) terminology

Fig. 1. A partial view of the reinerite structure, showing the atom nomenclature and the ellipsoids of thermal vibration.
this is a Zweier-Doppelkette or a double chain with two-tetrahedral repeat, accounting for the 6.09A $a$ axis. These double chains are comparable to the am-phibole-type silicate double chains. However, the double chains with the composition $\left[\mathrm{Zn}_{4} \mathrm{O}_{10}\right]$ in reinerite are characterized by four-membered rings, as opposed to six-membered rings in the $\left[\mathrm{Si}_{4} \mathrm{O}_{11}\right]$ double chains of amphiboles.

The $\mathrm{Zn}(2) \mathrm{O}_{4}$ tetrahedron (av. $\mathrm{Zn}-\mathrm{O}$ distance 1.964 A ) shows considerable angular distortion, the $\mathrm{O}-\mathrm{Zn}-\mathrm{O}$ angle ranging from 99.9 to $119.6^{\circ}$.

## (c) The arsenite groups

Both the $\mathrm{AsO}_{3}$ groups are trigonal pyramids with point symmetry $m$, deviating significantly from the highest possible point symmetry 3 m . The average As-O bond length and the pyramidal edge ( $\mathrm{O}-\mathrm{O}$ ) distances are 1.769 and 2.661 A respectively, and the average O -As-O angle is $97.6^{\circ}$. Other than the closest three oxygens, no oxygen atoms approach the relatively unshielded $\mathrm{As}^{3+}$ ion within 3.5 A .

## (d) The three-dimensional framework

The backbone of the reinerite structure is the tetrahedral double chain running parallel to the $a$ axis. Such double chains are cross-linked through Zn -tetrahedral dimers by corner-sharing, giving rise to a second type of Zn -tetrahedral corrugated chain running parallel to the $c$ axis (Fig. 4b). Such a framework is further strengthened by pyramidal arsenite groups sharing corners of two adjacent double chains with a corner of the Zn -tetrahedral dimer (Fig. 3). Each oxygen atom is being shared by two zinc and one arsenic atoms.

## Discussion

## Configuration of the arsenite group

The accurate configuration of the trigonal-pyramidal $\mathrm{As}^{3+} \mathrm{O}_{3}$ groups has been determined in relatively few minerals. In trippkeite, $\mathrm{CuAs}_{2} \mathrm{O}_{4}$, the As-O distances are: $1.89(\times 2), 1.69 \mathrm{~A}$ (av. 1.82 A ), where the arsenite groups share corners to form chains (Zemann, 1951). In synadelphite, $\mathrm{Mn}_{9}(\mathrm{OH})_{9}$ $\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\left(\mathrm{AsO}_{3}\right)\left(\mathrm{AsO}_{4}\right)_{2}$ (Moore, 1970), asbecasite, $\mathrm{Ca}_{3} \mathrm{Ti}\left(\mathrm{As}_{3} \mathrm{SiBeO}_{10}\right)_{2}$ (Canillo et al. 1969), and in finnemanite, $\mathrm{Pb}_{5} \mathrm{Cl}\left(\mathrm{AsO}_{3}\right)_{3}$ (Gabrielson, 1956), the As-O distance within the isolated arsenite groups are 1.76, 1.797, and 1.81 A respectively. The av. $\mathrm{As}^{3+}-\mathrm{O}$ distance ( 1.769 A ) within the arsenite groups in reinerite is significantly shorter than all those mentioned above, except in synadelphite. It appears that the $\mathrm{As}^{3+}-\mathrm{O}$ bond length is highly variable. However, some of the structures mentioned above, when refined by modern methods, may show much less variation in the $\mathrm{As}^{3+}-\mathrm{O}$ bond length.

Crystal chemistry of the tetrahedral $\left[\mathrm{ZnO}_{4}\right)^{6-}$ ion: a comparison with the crystal chemistry of silicates

The facility of the $\left[\mathrm{SiO}_{4}\right]^{4-}$ ion to polymerize, giving rise to chains, rings, sheets, and framework structures, is well known. The tetrahedral $\left[\mathrm{ZnO}_{4}\right]^{6-}$ ion is emerging in a similar rôle. Thus, a corner-sharing pyroxene-type $\left[\mathrm{ZnO}_{3}\right]$ tetrahedral chain is found in

Fig. 2. A partial view of the reinerite structure down the $b$ axis, showing the tetrahedral edge-sharing $\left[\mathrm{Zn}_{2} \mathrm{O}_{6}\right]$ dimers and tetrahedral corner-sharing $\left[\mathrm{Zn}_{4} \mathrm{O}_{10}\right]$ double chains.

Fig. 3. A view of the reinerite structure down the $a$ axis; the $\left[\mathrm{Zn}_{4} \mathrm{O}_{10}\right]$ double chains are projected end on.

Fig. 4. (a) The $\left[\mathrm{Zn}_{4} \mathrm{O}_{10}\right]$ double chain in reinerite. (b) The corrugated tetrahedral chain with four-tetrahedral repeat in reinerite.
gerstmannite, $(\mathrm{Mn}, \mathrm{Mg}) \mathrm{Mg}(\mathrm{OH})_{2}\left[\mathrm{ZnSiO}_{4}\right]$ (Moore and Araki, 1977). The $\left[\mathrm{Zn}_{4} \mathrm{O}_{10}\right]_{\infty}$ double chain found in reinerite rivals the $\left[\mathrm{Si}_{4} \mathrm{O}_{11}\right]_{\infty}$ double chain in amphiboles; furthermore, the corrugated chain in reinerite is similar to the corrugated silicate chains found in alamosite, $\mathrm{Pb}_{12} \mathrm{Si}_{12} \mathrm{O}_{36}$ (Boucher and Peacor, 1968), and in stokesite, $\mathrm{Ca}_{2} \mathrm{Sn}_{2} \mathrm{Si}_{6} \mathrm{O}_{18}$ (Vorma, 1963). However, the corrugated chain in reinerite is a ViererEinfachkette, whereas the silicate chains in alamosite and stokesite are Zwölfer-Einfachkette and Sechser-Einfachkette respectively.

## Acknowledgment

We are greatly indebted to Mr. John S. White, Jr., of the Smithsonian Institution for the donation of this rare mineral for our investigation.
