# Three-layer monoclinic lepidolite from T申rdal, Norway 

S. W. Bailey<br>Department of Geology and Geophysics, University of Wisconsin<br>Madison, Wisconsin 53706<br>and Olav H. J. Christie<br>Laboratory for Mass Spectrometry, University of Oslo<br>P. O. Box 1048, Blindern, Oslo 3, Norway

#### Abstract

A 3-layer monoclinic lepidolite from a pegmatite at Tørdal, Norway, previously described as 2-layer orthorhombic, has been identified as the $3 M_{2}$ polytype. The space group is $C 2$ with $a$ $=5.239(2), b=9.070(3), c=29.886(5) \mathrm{A}$, and $\beta=92.58(2)^{\circ}$. The X-ray powder pattern differs in detail from those of the conventional mica polytypes. Electron microprobe analysis gives $\mathrm{SiO}_{2} 48.78, \mathrm{Al}_{2} \mathrm{O}_{3} 23.87, \mathrm{FeO}$ 1.39, $\mathrm{MgO} 0.02, \mathrm{MnO} 4.61, \mathrm{TiO}_{2} 0.07, \mathrm{~K}_{2} \mathrm{O} 9.88, \mathrm{Na}_{2} \mathrm{O}$ $0.20, \mathrm{BaO} 0.03, \mathrm{~F} 6.21$ weight percent for the $3 M_{2}$ flakes and $\mathrm{SiO}_{2} 53.41, \mathrm{Al}_{2} \mathrm{O}_{3} 21.43, \mathrm{FeO}$ $0.06, \mathrm{MgO} 0.02, \mathrm{MnO} 1.82, \mathrm{TiO}_{2} 0.06, \mathrm{~K}_{2} \mathrm{O} 9.85, \mathrm{Na}_{2} \mathrm{O} 0.19, \mathrm{BaO} 0.03, \mathrm{~F} 7.63$ weight percent for associated $2 M_{1}$ lepidolite flakes.

Heinrich et al. (1953) described a 3-layer monoclinic lepidolite from a pegmatite at Skuleboda, Sweden. Neumann et al. (1957) and Christie (1961) have described other lepidolite specimens from pegmatites at Varuträsk, Sweden, and Tørdal, Norway, that give X-ray powder patterns similar to that of the Skuleboda specimen. This note reports a more detailed study of the Tørdal material.

Single-crystal X-ray precession photographs of over 50 individual flakes of lepidolite from Tørdal showed three polytypic structures to be present-1M, $2 M_{1}$, and $3 M$. The $3 M$ flakes represent the same material that was originally described as 2-layer orthorhombic by Christie (1961).

The $3 M$ lepidolite has diffraction symmetry that could be described as $C 2 / m, C 2$, or $C m$. Single-crystal intensities were collected on an automated Syntex diffractometer and used for comparison with intensities calculated from the six possible 3-layer stacking sequences. Good agreement was found for only one model, which has ideal symmetry C2. Relative to a fixed initial set of axes, the intralayer shifts of $a / 3$ in this model are directed in the sequence $-X_{1}$, $+X_{2}$, and $-X_{3}$ within the three successive layers. The resultant shift then is $a / 3$ along $-X_{2}$ of the initial axes to give an ideal $\beta$ angle of $93.4^{\circ}$.

The structure deduced above is identical to the ideal structure described as $3 M_{2}$ by Ross et al. (1966) in their systematic study of possible mica polytypes. Comparison of Weissenberg photographs of the T $\phi$ rdal specimen with those illustrated by Heinrich et al. (1953, Figs. 10-12) indicates that the latter specimens also have the $3 M_{2}$ structure.

Table 1 lists the powder pattern of a pure sample of lepidolite- $3 M_{2}$ from T $\phi$ rdal. Indexing was achieved by direct comparison of the powder data with observed single-crystal intensities. The pattern differs in detail from those of the conventional mica structures and is characterized by the occurrence of several nonoverlapping triplets of indices $\overline{1} 1 l, 02 l$, and $11 l$. Leastsquares refinement of the powder data gave cell dimensions $a=5.239(2), b=9.070(3), c=29.886(5) \mathrm{A}$, and $\beta=92.58(2)^{\circ}$.

Table 2 lists electron microprobe analyses of flakes of $3 M_{2}$ and $2 M_{1}$ lepidolite from T申rdal. Although this method does not give Li or OH , the high F contents and the individual oxide totals are characteristic of lepidolite. The $3 M_{2}$ flake has less $\mathrm{SiO}_{2}$ than the $2 M_{1}$ flake but higher $\mathrm{Al}_{2} \mathrm{O}_{3}, \mathrm{MnO}$, and Fe (expressed as FeO ) contents. The $\mathrm{Li}_{2} \mathrm{O}$ contents must be approximately 4 to 5 weight percent for each flake,
