

## 67. *Parasymplesite, a New Mineral Polymorphous with Symplesite*

By Tei-ichi ITO, M.J.A., Hideo MINATO, and Kin'ichi SAKURAI

Mineralogical Institute, University of Tokyo

(Comm. April 12, 1954)

Symplesite from Felsöbánya was first described by Krenner as a monoclinic crystal.<sup>1)</sup> Wolfe investigated with X-rays the same mineral from Lobenstein and demonstrated the triclinic nature of its lattice.<sup>2)</sup> Unaware of Wolfe's work we analysed the crystal structure of symplesite using the fine vivianite-like specimens from Kiura, Japan.<sup>3,4)</sup> As revealed by this study the crystals from Kiura are not triclinic but monoclinic in symmetry, being closely related to vivianite in structure. On the other hand, our recent re-examination of the original symplesite from Felsöbánya and from Lobenstein, which were kindly put at our disposal by Professor Clifford Frondel of Harvard University, has confirmed in every detail the findings of Wolfe and has placed the dimorphism of symplesite beyond question. We therefore propose here the new name *parasymplesite* (in analogy with parawollastonite,<sup>5)</sup> paracelsian<sup>6)</sup> etc.) for the monoclinic variety of symplesite whose structure we worked out, retaining, following Frondel,<sup>7)</sup> the name *symplesite* for the triclinic variety originally described by Krenner and revised by Wolfe.

### Occurrence

Parasymplesite from Kiura, Ohita (Bungo), Japan occurs in the contact zone of limestone with granitic diorite, forming usually radiating aggregates of fine crystals grown on massive limonite, an alteration product of various ore minerals (scorodite, arsenopyrite etc.) constituting the deposits.<sup>4)</sup> It is these crystals we describe below.

### Crystallography

The crystals of parasymplesite are about  $3 \times 1.5 \times 1$  mm in dimensions and dark to light greenish blue in colour. Crystals are thick tabular after (010), with large  $b(010)$  and  $w(\bar{2}01)$  (Fig. 1a) or stout-prismatic with  $m(110)$  and other prisms nearly equally well developed and with relatively large  $E(502)$  (Fig. 1b). The unit

$\beta = 103^\circ 50'$

$K\alpha, \lambda = 0.71$

prismatic faces are observed in both types of crystals, other kinds of faces being only occasionally noticed.

Fig. 1. Parasymplesite from Kiura

The results of measurement by means of a Goldschmidt two-circle reflexion goniometer are given in Table I. The axial ratio has been deduced from the structural data (given below) as follows:

$$a : b : c = 0.760 : 1 : 0.350, \beta = 103^{\circ}50'.$$

Table I. Two-circle goniometry of parasymplesite

$\rho_c$  and  $\varphi_c$  calculated on the basis of the axial ratio:  $a:b:c=0.760:1:0.350$ ,  $\beta=103^{\circ}50'$ , deduced from the structural data

The unit cell has the dimensions:  $a=10.25\text{\AA}$ ,  $b=13.48\text{\AA}$ ,  $c=4.71\text{\AA}$ ,  $\beta=103^{\circ}50'$ ,<sup>3)</sup> containing two molecules of  $\text{Fe}_3(\text{AsO}_4)_2 \cdot 8\text{H}_2\text{O}$  (Mo  $K\alpha$ ,  $\lambda=0.710\text{\AA}$ ). The space group is  $C2/m$ .

We reproduce in Figs. 2 and 3, the 0-layer Weissenberg photographs of parasymplectite and symplectite (twinned on  $(1\bar{1}0)$ ), taken with a Wiebenga integrating X-ray goniometer both about the  $c$  axis (Fe  $K\alpha$ ). The X-ray powder photographs, and 'Norelco' spectrograms (Co  $K\alpha$ ) of symplectite and parasymplectite are compared

a) Parasymplectite

b) Symplectite

Fig. 2. Weissenberg photographs of parasymplectite and symplectite.  $c$ -axis, 0-layer. Fe radiations, no filter. Camera diameter 57.3 mm. Coupling 1mm to  $2^\circ$

in Figs. 4 and 5. The difference as well as similarity of the two minerals in symmetry and texture is well evidenced on these diagrams. (Also see Table II.)

### Chemical Composition

The chemical analysis of parasymplesite has been carried out by one of the present writers (H. M.) on the specimens which were separated from scorodite and other associated minerals with the result:  $As_2O_5$  38.43%,  $Fe_2O_3$  0.81%,  $FeO$  37.70%,  $MgO$  non,  $CaO$  non,  $P_2O_5$  non,  $H_2O(+)$  12.70%,  $H_2O(-)$  10.67%, Total 100.33%. This may be represented by the formula,  $Fe_{3.03}As_{1.99}O_8 \cdot (H_2O)_{4.08+3.43'}$  or very closely  $Fe_3(AsO_4)_2 \cdot 8H_2O$ .

### Optical and Other Physical Properties

The optical data are given in Table III. Cleavage is very perfect after (010). Hardness 2. The density has been determined with a pycnometer to be  $3.07 \text{ gr/cm}^3$  at  $20^{\circ}\text{C}$  against  $3.097 \text{ gr/cm}^3$  calculated on the basis of the X-ray data above given.
