# The graphical determination of the constants of a shear. 

By Harold Hilton, M.A., D.Sc.<br>Professor of Mathematics in Belford College (University of London).

[Read June 27, 1922.]

RECENTLY A. Johnsen ${ }^{1}$ has given a graphical solution by means of the stereographic projection of the problem of determining the constants of a homogeneous shear of a crystal, knowing the initial and final indices of two faces or two edges.

The same problem may be solved more easily by means of the gnomonic projection.

In a shear there are two fixed lines $l, m$ intersecting at right angles at $O$, such that each particle of the crystal moves parallel to $l$ through

a length proportional to its distance from the plane $l m$. The shear is considered given when we know $l, m$, and the line through $O$ perpendicular to $m$ making supplementary angles with $l$ before and after the shear.

Suppose we form the gnomonic projection of the face-poles and zones of the crystal from a sphere with centre $O$. Let $V$ be the centre of

[^0]the gnomonic projection, i. e. the point where the plane of the projection II touches the sphere. Suppose also we know the intersections ( $P, Q$ before shearing and $P^{\prime}, Q^{\prime}$ after) with $\Pi$ of the lines through $O$ parallel to two edges of the crystal.

Let $P P^{\prime}$ and $Q Q^{\prime}$ meet in $L ; P Q$ and $P^{\prime} Q^{\prime}$ meet in $H$.
Let the. line joining $H$ to the intersection of $P Q^{\prime}$ and $P^{\prime} Q$ meet $P P^{\prime}$ in $K$. Let $V K$ meet $L H$ in $U$. Let $P U, P^{\prime} U$ meet $L V$ in $R, R^{\prime}$. Then $L$ is the intersection of $l$ with $\Pi, L H$ is the intersection of the plane $l m$ with $\Pi$, and $O R$ is zone-axis brought to $O R^{\prime}$ by the shear, such that $O R$ and $O R^{\prime}$ are perpendicular to $m$ and make supplementary angles with $l$.

For the proof of the construction we notice that (1) it is a construction which is not altered by ordinary conical (plane-to-plane) projection; (2) a change of the plane of gnomonic projection is equivalent to a conical projection; (3) the construction is evidently correct when II is parallel to the plane $l m$, for then $P P^{\prime}, Q Q^{\prime}, R R^{\prime}$ are equal and parallel.

If the initial and final projections $A$ and $A^{\prime}, B$ and $B^{\prime}$ of two face-poles are given, instead of the intersections with $\Pi$ of lines through $O$ parallel to two edges, then $A A^{\prime}, B B^{\prime}$ meet in the intersection with II of the line through $O$ perpendicular to the plane $l m$.

Knowing $V$, we get thus the line LH. Moreover, the initial and final positions $A B$ and $A^{\prime} B^{\prime}$ of a zone are known, so that we can get $L$ and proceed as before.
