| $\mathrm{Ag}_{2} \mathrm{O}$ | - | - | 0.002 | $0 \cdot 002$ | - | - |

In conclusion, precious opal is similar to the associated common opal with respect to the following mineralogical properties: X-ray diffraction pattern, trace element content, thermogravimetric curves, and differential thermal curves.

The authors acknowledge with gratitude the assistance of Mr. L. Rannit of the School of Chemistry, University of New South Wales, for the semiquantitative spectrographic analyses listed in table I.

## Berek compensator

In determining the retardation, $\Gamma$, of a mineral with a Berek compensator, the expression $\Gamma=C . f(i)$ is used, where $C$ is the compensator constant and $f(i)$ is a function of the average angle of rotation, $i$, measured from the zero position of the compensator. The values of $C$ and
$f(i)$ can be obtained either from the makers' tables, or, when the tables are lost, from the procedure given by Naidu. ${ }^{1}$ In the method of Naidu, the $f(i)$ values are obtained by using the Berek's expression:

$$
f(i)=\sin ^{2} i\left\{1+0.2040 \sin ^{2} i+0 \cdot 0627 \sin ^{4} i\right\}
$$

The authors find that the above expression can be replaced by a simpler expression:

$$
f(i) \approx\left\{\left(i-\epsilon_{i}\right) \pi / 180\right\}^{2} \approx 0.000305\left(i-\epsilon_{i}\right)^{2}
$$

where $\epsilon_{i}$ is a small correction to the measured $i$ value, within the accuracy of the instrumental observations (tabulated below). Although no mathematical proof could be offered for the above expression, it was found that the calculated $\log f(i)$ values for all possible $i$ values are either equal to the values given in the makers' tables or greater by an amount not exceeding 0.004 .

| Range in $i$ | $\epsilon_{i}$ |
| ---: | :---: |
| $<16.5$ | 0.0 |
| 16.6 to 20.6 | 0.1 |
| 20.7 to $24 \cdot 0$ | 0.2 |
| $24 \cdot 1$ to 26.8 | 0.3 |
| 26.9 to $28 \cdot 6$ | 0.4 |
| 28.7 to 30.7 | 0.5 |
| 30.8 to $32 \cdot 0$ | 0.6 |
| $32 \cdot 1$ to 33.7 | 0.7 |
| 33.8 to 34.5 | 0.8 |

In determining the birefringence of a mineral by the 'comparisonmineral method', the following expression, which makes use of neither the section thickness nor the compensator constant, may be used: $\delta_{x} / \delta_{y}=f(i)_{x} / f(i)_{y}$, where $\delta_{x}$ and $\delta_{y}$ are the birefringences and $f(i)_{x}$ and $f(i)_{y}$ are the $f(i)$ values of the unknown and the comparison minerals respectively. On substituting the values of $f(i)_{x}$ and $f(i)_{y}$, according to the proposed expression, $\delta_{x} / \delta_{y}=\left(i_{x}-\epsilon_{i}^{\prime}\right)^{2} /\left(i_{y}-\epsilon_{i}^{\prime \prime}\right)^{2}$, where $\epsilon_{i}^{\prime}$ and $\epsilon_{i}^{\prime \prime}$ are the corrections to be made to $i_{x}$ and $i_{y}$ respectively.

Thus the above expression can be used for the determination of birefringence, without using the makers' tables, to a reasonable accuracy.
