TWO SAPPHIRINE LOCALITIES IN NEW QUEBEC

F. C. TAYLOR
Geological Survey of Canada, 588 Booth Street, Ottawa, Ontario KIA 0E4

ABSTRACT

Two sapphirine localities are reported in New Quebec, one near Cape Hopes Advance (1) and the other at Lake Sirmiq (2). These are associated with granulite and amphibolite (retrograded granulite) facies rocks. Microprobe analyses lead to the following structural formulae: (1) \((\text{Mg}_{0.8}\text{Fe}^{2+}_{0.7})(\text{Al}_{1.8}\text{Fe}^{3+}_{0.2}\text{Cr}_{0.5})(\text{Al}_{4.6}\text{Si}_{1.6})\text{O}_{26}\); (2) \((\text{Mg}_{0.2}\text{Fe}^{2+}_{0.5}\text{Cr}_{0.1})(\text{Al}_{4.8}\text{Si}_{1.6})\text{O}_{26}\).

Keywords: sapphirine, New Quebec, granulite-facies rocks, Lake Sirmiq, Cape Hopes Advance.

Despite its prominent blue color, sapphirine is rarely reported from the Canadian Shield. Higgins et al. (1979) listed only three occurrences. It has now been identified in rocks from two other localities, both in New Quebec.

Westra (1978) discovered sapphirine in a suite of metamorphic rocks collected during a reconnaissance mapping project by the Geological Survey of Canada in 1973 (Taylor 1974). This sapphirine, which occurs only in microscopic amounts, is from 7 km southwest of Cape Hopes Advance (Lat. 61°02'N, Long. 69°35'W). It is associated with spinel as small inclusions in garnet in an amphibolite-facies metamorphic rock retrograded from the granulite facies. Hornblende, biotite, quartz and plagioclase also are present. Westra gave results of a provisional electron-microprobe chemical analysis of the sapphirine (Table 1).

During the same mapping project, a second and previously unreported occurrence of sapphirine was sampled by J.B. Henderson on the northeast shore of Lake Sirmiq (Lat. 62°14'N, Long. 76°35'W). There, macroscopic amounts of sapphirine, with some grains up to 2 cm long, are associated and intergrown with hypersthene, biotite, plagioclase and quartz. This fresh rock is in the granulite metamorphic facies. Seven electron-microprobe analyses, three each of cores and edges of large grains and one of a small grain, show similar composition throughout. An average of these 7 analyses is shown in Table 1.

In addition to the results of microprobe analyses, Table 1 shows the structural formulae based on 20 oxygens and assumptions of cation occupancy of 14 sites, charge balance and stoichiometry following the method of Higgins et al. (1979).
