# The Crystal Structure of Ammonium Beryllium Fluoride, $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{BeF}_{4}$. 

By<br>Ralph Hultgren ${ }^{1}$ ) in Cambridge, Mass.

(With one figure.)

#### Abstract

The orthorhombic crystal, $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{BeF}_{4}$, has been investigated by the use of complete rotation and oscillation photographs. It is found that $a_{0}=5.8 \AA$, $b_{0}=10.2 \AA$, and $c_{0}=7.5 \AA$. The atomic arrangement is that of $K_{2} S O_{4}$, which structure is also assumed by $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}$. This shows that the $\mathrm{BeF} \mathrm{F}_{4}^{2-}$ group has much the same size and shape as the $S O_{4}^{2-}$ group, which is to be expected from consideration of ionic sizes.

Crystallographic investigations of ammonium beryllium fluoride $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{BeF}_{4}$, have shown that it is orthorhombic bipyramidal with axial ratios $a: b: c=0.5688: 1: 0.7367^{2}$ ). It is isomorphous with $K_{2} B e F_{4}$, but not with $\mathrm{Na}_{\mathbf{2}} \mathrm{BeF}_{4}$.

Well formed crystals of it were made available to me through the kindness of Mr. Charles F. Hill, of this laboratory, who had prepared them in the course of another investigation. The crystals consisted of plates flattened along the $c$ axis and longer along the $a$ axis than along the $b$. Prominent faces were (001), (010), and (110).

## The Unit of Structure and Space-group Symmetry.

Complete rotation photographs were made about all three axes with Mo radiation filtered through zirconia and the size of the unit cell was found to be

$$
a_{0}=5.8 \AA \quad b_{0}=10.2 \AA \quad c_{0}=7.5 \AA
$$

to an accuracy of about $0.1 \AA$. This agrees well with the axial ratios listed by Groth. If the unit cell contains four molecules, the calculated density is $1.80 \mathrm{~g} / \mathrm{cm}^{3}$. This value was roughly verified by weighing a

[^0]Zeitschr. f. Kristallographie. 88. Bd.
crystal and computing its volume from micrometer measurements of its dimensions.

Eight oscillation photographs were taken about (010) and two about (100) in such a way that all planes would have the opportunity to reflect. The angle of oscillation was $16^{\circ}$ in each case. Reflections were absent from planes ( $h k 0$ ) with $h+k$ odd, and from ( $h 0 l$ ) where $l$ was odd. Since the crystallographic symmetry is holohedral, all space groups are eliminated except $V_{h}^{1}, V_{h}^{5}, V_{h}^{13}$, and $V_{h}^{16}$. The last is the only one which requires both extinctions and is much the most probable. The space group is thus determined to be:

$$
V_{h}^{16}-P m c n .
$$

## The Atomic Irrangement.

The following possible positions are provided by this space group:

| (a) | $000 ;$ | $\frac{1}{2} 00 ;$ | $\frac{1}{2} \frac{1}{2} \frac{1}{2} ;$ | $0 \frac{1}{2} \frac{1}{2}$ |
| :--- | :---: | :---: | :---: | :---: |
| (b) | $0 \frac{1}{2} 0 ;$ | $\frac{1}{2} \frac{1}{2} 0 ;$ | $\frac{1}{2} 0 \frac{1}{2} ;$ | $00 \frac{1}{2}$ |
| $(c)$ | $\frac{1}{4} u v ;$ | $\frac{1}{4}, \frac{1}{2}-u, \frac{1}{2}+v$, | $\frac{3}{4}, \frac{1}{2}+\mu, \frac{1}{2}-v ;$ | $\frac{3}{4} \bar{u} \bar{v}$ |
| (d) | $x y z ;$ | $\frac{1}{2}-x, y, z ;$ | $x, \frac{1}{2}-y, \frac{1}{2}+z ;$ | $\frac{1}{2}+x, \frac{1}{2}+y, \frac{1}{2}-z ;$ |
|  | $\bar{x} \bar{y} \bar{z} ;$ | $\frac{1}{2}+x, \bar{y}, \bar{z} ;$ | $\bar{x}, \frac{1}{2}+y, \frac{1}{2}-z ;$ | $\frac{1}{2}-x, \frac{1}{2}-y, \frac{1}{2}+z$. |

The origin of coordinates is here taken at a center of symmetry. Positions $(a)$ and $(b)$ are at centers of symmetry, $(c)$ is on a plane of symmetry, while $(d)$ is the general position. If the $B e^{2+}$ ions are surrounded by four $F^{-}$ ions at the corners of a regular tetrahedron, as seems almost certain, they cannot lie at a center of symmetry, but must lie at (c), on the plane of symmetry. Furthermore, in the $B e F_{4}^{2-}$ group, two of the $F^{-}$ions must lie on the plane in positions ( $c$ ) and the other two off the plane at $(d)$. The $\mathrm{NH}_{4}^{+}$ions can be shown to lie on the plane from intensity considerations.

Thus it is observed that (200) is slightly stronger than (400), while (600) weakly reflects. If we assume the reasonable value of $1.64 \AA$ for the $B e-F$ distance and place the $F^{-}$ions at the corners of a regular tetrahedron, then all the $x$ coordinates are fixed except those of $N H_{4}^{+}$. If these are placed in positions $(d)$, it is found that the calculated intensity from (400) is much greater than (200) except near $x=\frac{1}{4}$. But an atom cannot lie nearer to a plane of symmetry than its own radius, so the position $(d)$ is excluded. The results of calculations for the other positions are shown in Table I.

Table I. Calculated Intensity.

|  | Both $N H_{4}^{+}$at <br> $(a)$ or $(b)$ | One $\mathrm{NH}_{4}^{+}$at <br> $(a)$ or $(b) ;$ <br> one at $(c)$ | Both $N H_{4}^{+}$ <br> at $(c)$ | Observed Inten- <br> sity |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{I}_{200}$ | 128 | 57 | 2060 | 6 |
| $\mathrm{I}_{400}$ | 2570 | 2570 | 2570 | 5 |
| $\mathrm{I}_{600}$ | 0 | 13 | 50 | 1 |

From Table I it is evident that the $N H_{4}^{+}$ions lie in two sets of positions (c). The small disagreement of calculated and observed intensities is probably due to the temperature factor, which was not considered. For the scattering factor of $N H_{4}^{+}$, the values assumed by Pauling ${ }^{1}$ ) were chosen. He assumed $f_{N H_{4}}^{+}=f_{N}+t_{o^{-}}-f_{0}$. It was later found that unpublished experimental values of Dr. G. A. Morton check these assumed values fairly closely except for small values of $\sin \theta / \lambda$, so no great error is to be anticipated here.

The atomic positions have thus been found to be:

```
\(\mathrm{NH}_{4}\) (1) at \(\frac{1}{4} u v ; \frac{1}{4}, \frac{1}{2}-u, \frac{1}{2}+v ; \frac{3}{4}, \frac{1}{2}+u, \frac{1}{2}-v ; \frac{3}{4} \bar{u} \bar{v}\)
\(\mathrm{NH}_{4}\) (2) at \(\frac{1}{4} u^{\prime} v^{\prime}\); etc.
    \(B e \quad\) at \(\frac{1}{4} u^{\prime \prime} v^{\prime \prime}\); etc.
    \(F\) (1) at \(\frac{1}{4} u_{1} v_{1}\); etc.
    \(F\) (2) at \(\frac{1}{2} u_{2} v_{2}\); etc.
    \(F\) (3) at \(x y z ; \frac{1}{2}--x, y, z ; x, \frac{1}{2}-y, \frac{1}{2}+z ; \frac{1}{2}+x, \frac{1}{2}+y, \frac{1}{2}-z\);
    \(\bar{x} \bar{y} \bar{z} ; \frac{1}{2}+x, \bar{y}, \bar{z} ; \bar{x}, \frac{1}{2}+y, \frac{1}{2}-z ; \frac{1}{2}-x, \frac{1}{2}-y, \frac{1}{2}+z\).
```

Rigorous determination of the atomic coordinates cannot be made because of the large number of parameters involved. However, it is noticed that all the atomic positions agree with those of $K_{2} S O_{4}$, which structure is also assumed by $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}$. The lengths of the axes are also nearly the same. In $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}, a_{0}=5.95, b_{0}=10.5, c_{0}=7.73 \AA$. It might be expected that $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{BeF}_{4}$ would assume this structure since the $B e F_{4}^{2-}$ group ought to be about the same size and shape as the $S O_{4}^{2-}$ group. Also each is isomorphous with its corresponding potassium salt and different from its sodium salt.

It was found that this structure does indeed give reasonably good agreement between calculated and observed intensities when the parameters are varied somewhat. Values of parameters yielding best agreement are given in Table II. along with those of $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}$ for comparison. The agreement between calculated and observed intensities is shown in

[^1]Table III. It was felt that this agreement could be improved by further variation of the parameters, as the intensities are quite sensitive, but such changes in the parameters would be small and it was not thought worth while.

Table II. Parameters of Structure

|  | 114 | 17 | 1 |  |  |  |  |
|  | 124 | 102 | 2 |  |  |  |  |

The structure is shown in the diagram. Each $B e^{2+}$ is surrounded by four $F^{-}$at the corners of a regular tetrahedron at a distance of $1.61 \AA$. Half of the $\mathrm{NH}_{4}^{+}$ions are surrounded as follows: $3 F^{-}$at $2.81 \AA, 2 \mathrm{~F}^{-}$at $2.92 \AA, 3 F^{-}$at $3.04 \AA$. The other half have $1 F^{-}$at $2.79 \AA, 3 F^{-}$at $2.82 \AA$,

Fig. 1. Structure of $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{BeF}_{4}$.
and $5 F^{-}$at $2.98 \AA$. There is no particular indication of hydrogen bonds between $N$ and $F$, such as $\mathrm{Pauling}^{1}$ ) found for $N H_{4} F$, but the data are not sufficiently accurate to exclude them. The interionic distances agree with what should be expected.

I am indebted to Professor B. E. Warren for many helpful suggestions in carrying out this work.
