ABSTRACT

Agaite, $\text{Pb}_3\text{Cu}^{2+}\text{Te}^{6+}\text{O}_5(\text{OH})_2(\text{CO}_3)$, is a new tellurate from the Aga mine on Otto Mountain near Baker, California, U.S.A. The new mineral is known from only one specimen. It occurs on quartz in association with cerussite, Br-rich chlorargyrite, chrysocolla, goethite, khinite, markcooperite, muscovite, phosphohedyphane, timroseite, and wulfenite. It is interpreted as having formed from the partial oxidation of primary sulfides and tellurides during or following brecciation of quartz veins. Agaite is orthorhombic, space group $Pca2_1$, with unit-cell dimensions $a = 10.6522(7)$, $b = 9.1630(5)$, $c = 9.6011(7)$ Å, $V = 937.12(11)$ Å³, and $Z = 4$. Agaite crystals form as blades flattened on {010} and probably elongated on [001], and are up to about 20 µm thick and 200 µm in length. The color is blue, the streak is pale blue, and the luster is adamantine. The Mohs hardness is estimated at between 2 and 3. Agaite is brittle with an irregular fracture and one perfect cleavage on {010}. The calculated density based on the empirical formula is 6.987 g/cm³. Agaite is biaxial (−), with calculated indices of refraction of $\alpha = 2.015$, $\beta = 2.065$, and $\gamma = 2.070^\circ$. The measured $2V$ is 34(5)° and the optical orientation is $X = \mathbf{b}$, $Y = \mathbf{c}$, and $Z = \mathbf{a}$. It is pleochroic: X = pale blue, Y and Z = blue; $X < Y = Z$. Electron microprobe analyses (average of 4) provided: PbO 65.91, CuO 7.75, TeO₃ 17.41, CO₂ 4.33 (structure), H₂O 1.78 (structure), total 97.18 wt%. The empirical formula (based on 10 O apfu) is: $\text{Pb}_{3.00}\text{Cu}_{0.99}^{2+}\text{Te}_{1.01}^{6+}\text{O}_5(\text{OH})_2(\text{CO}_3)$. The eight strongest powder X-ray diffraction lines are [d_{obs} in Å (hkl) I]: 4.26 (012) 28, 4.165 (211) 14, 3.303 (022, 310, 221) 100, 2.7472 (131, 203, 312) 68, 2.571 (032, 401, 231) 14, 2.0814 (332, 422) 21, 2.0306 (511) 17, and 1.7468 (multiple) 40. The crystal structure of agaite ($R_1 = 0.033$ for 1913 reflections with $F_o > 4\sigma F$) contains edge-sharing chains of Cu²⁺O₅ square pyramids and Te⁶⁺O₆ octahedra parallel to \mathbf{a} that are joined by corner-sharing in the \mathbf{c} direction, forming a polyhedral sheet parallel to {010}. The polyhedral sheet is very similar to those in the structures of timroseite and paratimroseite. The thick interlayer region contains 8- and 9-coordinated Pb²⁺, as well as CO₃ and OH groups. The Pb coordinations have lopsided distributions of bond lengths attributable to the localization of the Pb²⁺ 6s² lone-pair electrons.

Keywords: Agaite, new mineral, tellurate, crystal structure, Pb²⁺ 6s² lone-pair, timroseite, para-timroseite, Otto Mountain, California

INTRODUCTION

The remarkable secondary mineral assemblage at Otto Mountain, near Baker, California, U.S.A. (Housley et al. 2011), has now yielded a total of 10 new Pb-Te oxysalts: ottoite, housleyite, thorneite, markcooperite, timroseite, paratimroseite, telluroperite, chromschieffelite, fuettererite, and agaite (see Table 1). The last of these, agaite, is described herein. Agaite is named for the type locality, the Aga mine, and for A.G. Andrews, from whose initials the name of the mine is derived. Andrews is one of two persons who are responsible for the development of the mining claims on Otto Mountain. In 1940, Otto Fuetterer filed six claims on the hill, named Good Hope 1–6. The following year, A.G. Andrews, a friend of Fuetterer, filed 18 adjacent claims named Aga 1–18; in 1942 Andrews added two more, Aga 19

and 20. The two men held these claims together until sometime after 1950 when Fuetterer became sole owner of all 26 claims.

The new mineral and name has been approved by the Commission on New Minerals, Nomenclature and Classification of the International Mineralogical Association (IMA 2011-115). One holotype specimen is deposited in the Natural History Museum of Los Angeles County, catalog number 63590.

OCCURRENCE

The only known specimen of agaite was found by one of the authors (J.M.) at the Aga mine (35.27215°N, 116.09487°W, elevation 1055 feet) on Otto Mountain, 1 mile northwest of Baker, San Bernardino County, California, U.S.A. On this specimen there is only one small cluster of agaite crystals on quartz in association with cerussite, Br-rich chlorargyrite, chrysocolla, goethite, khinite, markcooperite, muscovite, phosphohedyphane, timroseite, and wulfenite. Other species identified in the mineral

TABLE 1. New minerals described from Otto Mountain

| Mineral | Ideal Formula | Reference |
|-------------------|---|----------------------|
| Ottosite | Pb ₂ Te ⁶⁺ O ₅ | Kampf et al. (2010a) |
| Housleyite | Pb ₆ Cu ²⁺ Te ⁶⁺ O ₁₈ (OH) ₂ | Kampf et al. (2010b) |
| Thorneite | Pb ₆ (Te ⁶⁺ O ₁₀)(CO ₃)Cl ₂ (H ₂ O) | Kampf et al. (2010c) |
| Markcooperite | Pb ₂ (UO ₂)Te ⁶⁺ O ₆ | Kampf et al. (2010d) |
| Timroseite | Pb ₂ Cu ²⁺ (Te ⁶⁺ O ₆) ₂ (OH) ₂ | Kampf et al. (2010e) |
| Paratimroseite | Pb ₂ Cu ²⁺ (Te ⁶⁺ O ₆)(H ₂ O) ₂ | Kampf et al. (2010e) |
| Telluroperite | Pb ₂ Te ⁴⁺ O ₄ Cl ₂ | Kampf et al. (2010f) |
| Chromschieffelite | Pb ₁₀ Te ⁶⁺ O ₂₀ (CrO ₄)(H ₂ O) ₅ | Kampf et al. (2012) |
| Fuettererite | Pb ₂ Cu ²⁺ Te ⁶⁺ O ₆ (OH) ₂ Cl ₅ | Kampf et al. (2013) |
| Agaite | Pb ₂ Cu ²⁺ Te ⁶⁺ O ₅ (OH) ₂ (CO ₃) | This study |

assemblages at Otto Mountain include acanthite, anatacamite, anglesite, atacamite, boleite, brochantite, burckhardtite, calcite, caledonite, celestine, chalcopyrite, chromschieffelite, creaseyite, devilline, diaboleite, eztelite, fluorite, fornacite, frankhawthorneite, fuettererite, galena, gold, gypsum, hematite, hemimorphite, hessite, housleyite, iodargyrite, jarosite, kuranakhite, leadhillite, linarite, malachite, mattheadleyite, mcalpineite, mimetite, mottramite, munakataite, murdochite, ottoite, paratacamite, paratimroseite, perite, plumbojarosite, plumbotsumite, pyrite, sonoraite, sphalerite, thorneite, vanadinite, vauquelinite, and xocomacatlite.

Agaite and most of the other secondary minerals of the quartz veins are interpreted as having formed from the partial oxidation of primary sulfides (e.g., galena and chalcopyrite) and tellurides (e.g., hessite) during or following brecciation of the quartz veins. Additional background on the occurrence is provided in Kampf et al. (2010a) and Housley et al. (2011).

**FIGURE 1.** SEM image of agaite on quartz.

PHYSICAL AND OPTICAL PROPERTIES

Agaite occurs as blades flattened on {010} and probably elongated on [001] up to about 20 μm thick and 200 μm in length (Fig. 1). No twinning was observed optically under crossed polars or based upon single-crystal X-ray diffraction. The color is blue, the streak is pale blue, and the luster is adamantine. The Mohs hardness could not be measured, but is estimated to be between 2 and 3, based upon the behavior of crystals when broken. The new mineral is brittle with irregular fracture and one perfect cleavage on {010}. The density could not be measured because it is greater than those of available high-density liquids and there is insufficient material for physical measurement. The calculated density based on the empirical formula is 6.987 g/cm³ and that based on the ideal formula is 6.993 g/cm³. Insufficient material was available for chemical tests; however, it is likely that the mineral dissolves in cold, dilute HCl with some effervescence due to the presence of CO₃.

The indices of refraction could not be measured because of the small amount of material available and the difficulty in working with liquids of sufficiently high index of refraction. We have endeavored to provide optical properties based upon a combination of measurements and calculations. Agaite is biaxial (−), with indices of refraction $\alpha = 2.015$, $\beta = 2.065$, and $\gamma = 2.070$. These were calculated from the retardation, $\gamma - \beta = 0.005$ (measured with a Berek compensator), $2V_{\text{meas}} = 34(5)^\circ$ (measured on a spindle stage), and $n_{\text{av}} = 2.050$ (based upon the Gladstone-Dale relationship for the ideal composition; Mandarino 2007). The dispersion could not be observed. The optical orientation is: $X = \mathbf{b}$, $Y = \mathbf{c}$, and $Z = \mathbf{a}$. Agaite is pleochroic: $X = \text{pale blue}$, Y and $Z = \text{blue}$; $X < Y = Z$.

CHEMICAL COMPOSITION

Quantitative chemical analyses (4) of agaite were performed using a JEOL8200 electron microprobe (WDS mode, 15 kV, 5 nA, 1 μm beam diameter) at the Division of Geological and Planetary Sciences, California Institute of Technology. The standards used were: galena (for Pb), cuprite (for Cu), and Sb₂Te₃ (for Te). Analytical results are given in Table 2. No other elements were detected in EDS analyses. There was insufficient material for CHN analyses, so CO₂ and H₂O were calculated on the basis of 5 total cations (Pb + Cu + Te), charge balance and 10 total O apfu, as determined by the crystal-structure analysis (see below). Note that agaite is prone to electron beam damage, which contributes to the low analytical total. This is a common feature observed in most secondary tellurite species (e.g., Kampf et al. 2010a, 2010b, 2010c, 2010d, 2010e, 2012, 2013; Mills et al. 2009, 2010).

The empirical formula (based on 10 O apfu) is: Pb_{3.00}Cu_{2.99}Te_{1.01}O₅(OH)₂(CO₃). The simplified formula is Pb₃Cu²⁺Te⁶⁺O₅(OH)₂(CO₃), which requires PbO 67.86, CuO 8.06, TeO₃ 17.80, CO₂ 4.46, H₂O 1.83, total 100 wt%.

TABLE 2. Chemical analytical data for agaite

| Constituent | Average | Range | St.dev. |
|-------------------|---------|-------------|---------|
| PbO | 65.91 | 65.43–66.61 | 0.55 |
| CuO | 7.75 | 7.60–7.98 | 0.17 |
| TeO ₃ | 17.41 | 17.18–17.60 | 0.21 |
| CO ₂ * | 4.33 | | |
| H ₂ O* | 1.78 | | |
| Total | 97.18 | | |

* Based on the crystal structure.

X-RAY CRYSTALLOGRAPHY AND STRUCTURE DETERMINATIONS

All powder and single-crystal X-ray diffraction data were obtained on a Rigaku R-Axis Rapid II curved imaging plate microdiffractometer utilizing monochromatized MoK α radiation. Observed powder d -values (with standard deviations) and intensities were derived by profile fitting using JADE 9.3 software. Data (in angstroms) are given in Table 3. Unit-cell parameters refined from the powder data using JADE 9.3 with whole pattern fitting are: $a = 10.620(6)$, $b = 9.116(5)$, $c = 9.555(6)$ Å, and $V = 925.0(9)$ Å 3 . The observed powder data fit well with those calculated from the structure, also using JADE 9.3. The relatively low precision of the cell refined from the powder data are attributable to the use of MoK α radiation.

The Rigaku CrystalClear software package was used for processing of the diffraction data, including the application of an empirical multi-scan absorption correction using ABSCOR (Higashi 2001). The structure was solved by direct methods using SIR2004 (Burla et al. 2005). SHELXL-97 software (Sheldrick 2008) was used for the refinement of the structure. All sites were assigned full occupancy. Details concerning data collection and structure refinement are provided in Table 4. Fractional coordinates and atom displacement parameters are provided in Table 5, selected interatomic distances in Table 6, and bond valences in Table 7. (CIF and data set deposited online¹.)

¹ Deposit item AM-13-016, Data set and CIF. Deposit items are available two ways: For a paper copy contact the Business Office of the Mineralogical Society of America (see inside front cover of recent issue) for price information. For an electronic copy visit the MSA web site at <http://www.minsocam.org>, go to the American Mineralogist Contents, find the table of contents for the specific volume/issue wanted, and then click on the deposit link there.

DESCRIPTION OF THE STRUCTURE

The structure of agaite (Fig. 2) contains edge-sharing chains of Cu $^{2+}$ O₅ square pyramids and Te $^{6+}$ O₆ octahedra parallel to **a** that are joined by corner-sharing in the **c** direction, forming a polyhedral sheet parallel to {010} (Fig. 3). The Cu $^{2+}$ O₅ square pyramid exhibits typical Jahn-Teller distortion, with four short equatorial

bonds and one much longer apical bond. One equatorial edge is shared with a Te⁶⁺O₆ octahedron and one equatorial-apical edge is shared with a Te⁶⁺O₆ octahedron. The latter requires the apex of the square pyramid to be very markedly canted in the direction of the shared edge.

The thick interlayer region contains three different Pb²⁺-O coordinations, as well as CO₃ and OH groups. The CO₃ groups are aligned approximately parallel to {010} and are located midway between the polyhedral sheets. Pb1 is 9-coordinated and both Pb2 and Pb3 are 8-coordinated. All three Pb coordinations have lopsided distributions of bond lengths attributable to the localization of the Pb²⁺ 6s² lone-pair electrons (Fig. 4). The

Notes: Values are expressed in valence units. Pb²⁺-O bond strengths from Krivovichev and Brown (2001); C⁴⁺-O, Te⁶⁺-O, and Cu²⁺-O bond strengths from Brown and Altermatt (1985); hydrogen-bond strengths based on O-O bond lengths, also from Brown and Altermatt (1985).

FIGURE 3. The polyhedral sheets in the structures of agaite, timroseite, and paratimroseite. The sheets are essentially the same, if the unshaded CuO₅ and CuO₆ polyhedra in the sheets in timroseite and paratimroseite are ignored.

FIGURE 4. Pb coordinations in agaite. The lopsided distributions of bond lengths are attributable to the localization of the lone-pair electrons. Bond lengths are given in angstroms.

relatively weak bonding between the polyhedral sheets accounts for the perfect {010} cleavage.

The edge- and corner-sharing polyhedral sheet consisting of Cu²⁺O₅ square pyramids and Te⁶⁺O₆ octahedra in the structure of agaite is very similar to the sheets in the structures of timroseite and paratimroseite (Kampf et al. 2010e). In fact, the sheets are essentially identical if half of the Cu polyhedra in the timroseite and paratimroseite sheets are selectively removed as shown in Figure 3. Further evidence of the similarity of the sheets is provided by the cell parameters corresponding to the sheet dimensions: for agaite $a = 10.6522$ (2×5.3261) and $c = 9.6011$ Å; for timroseite $a = 5.2000$ and $b = 9.6225$ Å; and for paratimroseite $a = 5.1943$ and $b = 9.6198$ Å.

The only other known tellurate-carbonate, thorneite (Kampf et al. 2010c), is also found at Otto Mountain, but is found there at the Bird Nest drift and not at the Aga mine. As seen by its formula, Pb₆(Te₂O₁₀)(CO₃)Cl₂(H₂O), thorneite contains no Cu²⁺. Its crystal structure bears no resemblance to that of agaite and, in fact, it is the only mineral with a structure containing edge-sharing tellurate dimers.

ACKNOWLEDGMENTS

The paper benefited from comments by reviewers Fernando Colombo and Jiri Sejkora. The Caltech EMP analyses were supported by a grant from the Northern

California Mineralogical Association. The remainder of this study was funded by the John Jago Trelawney Endowment to the Mineral Sciences Department of the Natural History Museum of Los Angeles County.

_refine_special_details
;
Refinement of F^2^ against ALL reflections. The weighted R-factor wR and
goodness of fit S are based on F^2^, conventional R-factors R are based
on F, with F set to zero for negative F^2^. The threshold expression of
F^2^ > 2sigma(F^2^) is used only for calculating R-factors(gt) etc. and is
not relevant to the choice of reflections for refinement. R-factors based
on F^2^ are statistically about twice as large as those based on F, and R-
factors based on ALL data will be even larger.

_geom_special_details

 ;

All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
