Abstract: The new Mg- and F-dominant lamprophyllite-group mineral lileyite (IMA 2011-021) was found at the Löhley quarry, Üdersdorf, near Daun, Eifel Mountains, Rhineland-Palatinate (Rheinland-Pfalz), Germany, and named for the old name of the type locality, Liley. Associated minerals are nepheline, leucite, augite, magnetite, fluorapatite, perovskite, götzenite. Lileyite is brown, translucent; streak is white. It forms platy crystals up to $0.1 \times 0.3 \times 0.5$ mm in size and their clusters up to 1 mm across on the walls of cavities in an alkaline basalt. Lileyite is brittle, with Mohs hardness of 3–4 and perfect cleavage on (001). D_{calc} is 3.776 g/cm³. The new mineral is biaxial (+), $\alpha = 1.718(5)$, $\beta = 1.735(5)$, $\gamma = 1.755(5)$, 2V (meas.) = 75(15) $^\circ$, 2V (calc.) = 86 $^\circ$. The IR spectrum is given. The chemical composition is (EDS-mode electron microprobe, mean of 5 analyses, wt%): SiO₂ 28.05, BaO 26.39, TiO₂ 18.53, Na₂O 6.75, MgO 4.58, FeO 4.48, CaO 2.30, SrO 2.23, MnO 1.44, K₂O 1.41, Nb₂O₅ 0.95, F 3.88, –O=F₂ -1.63; total 99.36. The empirical formula based on 18 anions is: $\text{Ba}_{1.50}\text{Sr}_{0.19}\text{K}_{0.26}\text{Na}_{1.89}\text{Ca}_{0.36}\text{Mn}_{0.18}\text{Mg}_{0.99}\text{Fe}_{0.54}\text{Ti}_{2.01}\text{Nb}_{0.06}\text{Si}_{4.06}\text{O}_{16.23}\text{F}_{1.77}$. The simplified formula is: $\text{Ba}_2(\text{Na},\text{Fe},\text{Ca})_3\text{MgTi}_2(\text{Si}_2\text{O}_7)_2\text{O}_2\text{F}_2$. The crystal structure was solved using single-crystal X-ray diffraction data ($R = 0.024$). Lileyite is monoclinic, space group $C2/m$, $a = 19.905(1)$, $b = 7.098(1)$, $c = 5.405(1)$ Å, $\beta = 96.349(5)$ °, $V = 758.93(6)$ Å³, $Z = 2$. The strongest lines of the powder diffraction pattern [d , Å (I, %) (hkl)] are: 3.749 (45) (31–1), 3.464 (76) (510, 311, 401), 3.045 (37) (51–1), 2.792 (100) (221, 511), 2.672 (54) (002, 601, 20–2), 2.624 (43) (710, 42–1). Type material is deposited in the collections of the Fersman Mineralogical Museum of the Russian Academy of Sciences, Moscow, Russia, registration number 4106/1.

Key-words: lileyite, new mineral, lamprophyllite group, heterophyllosilicates, crystal structure, Eifel, Germany.

1. Introduction

Lamprophyllite-group minerals (Back & Mandarino, 2008) belong to the large family of heterophyllosilicates, *i.e.* minerals whose crystal structures are based on the HOH layers consisting of one inner octahedral (O) and two outer heteropolyhedral (H) sheets. The stoichiometry of heterophyllosilicates can be described by the following general formula (after Ferraris & Gula, 2005; some designations are changed): $A_2\{M_4[L_2X_{2+p}(\text{Si}_2\text{O}_7)_2]Y_2\}W$, where A are low-field-strength interlayer cations (typically, alkaline and alkaline-earth), M are octahedral cations of the O sheet, L are cations with 5- or 6-fold coordination

belonging to the H sheet, X and Y are O, F and OH; W are H₂O molecules and complex anions; $p = 0–2$.

Distinctive features of lamprophyllite-group minerals are: (a) the absence of W -components; (b) 5-fold coordination of L cations, and consequently zero p value. The general crystal chemical formula of lamprophyllite, barytolamprophyllite, ericssonite and ferroericssonite (Kampf *et al.*, 2011) is $[^{[10–11]}A_2\, [^{[6]}M_1\, [^{[6]}M_2\, [^{[6]}M_3\, X_2]\, [^{[5]}L_2\, (\text{Si}_2\text{O}_7)_2\text{O}_2]]$ where $A = \text{Ba, Sr, K, Na, Ca, } \square$; $M_1 = \text{Na, Mn}^{2+}$; $M_2 = \text{Na, Mn}^{2+}$, Fe^{2+} , Ca ; $M_3 = \text{Ti, Mn}^{2+}$, Mg, Fe^{3+} , Fe^{2+} ; $L = \text{Ti, Fe}^{3+}$; $X = \text{OH, O, F}$ (species-defining components of valid mineral species are given in bold type). In these minerals (Si_2O_7) groups link to the *trans*

edges of the same octahedron of the *O* sheet, unlike the related triclinic (space group *P*1) mineral schüllerite (Chukanov *et al.*, 2011) that has a different topology of the *HOH* layer corresponding to ‘linkage 3’ (Sokolova, 2006) where two (Si_2O_7) groups link to two octahedra adjacent approximately along the diagonal *yz*. In schüllerite and nabalamprophyllite (space group *P*2/*m*: Chukanov *et al.*, 2004) *A*-, *M*-, *L*- and *X*-sites are transformed in pairs of non-equivalent sites. For lamprophyllite, barytolamprophyllite and ericssonite two polytypes are known: 2*M* (space group *C*2/*m*) and 2*O* (space group *Pnnm*): Peng & Chang, 1965; Moore, 1971; Krivovichev *et al.*, 2003; Sokolova & Hawthorne, 2008. In the latter paper, the orthorhombic polytype of barytolamprophyllite is erroneously named ‘‘orthorhombic polytype of nabalamprophyllite’’. Nabalamprophyllite and barytolamprophyllite have different crystal-chemical formulae. Barytolamprophyllite, including the sample described by Sokolova & Hawthorne (2008), has one interlayer cation site that is Ba-dominant. Unlike barytolamprophyllite, nabalamprophyllite contains two interlayer cation sites, occupied predominantly with Na and Ba (Chukanov *et al.*, 2004).

The present paper is a description of a new mineral species, lileyite (Cyrillic: лилейит), and its crystal structure. Lileyite is a member of the lamprophyllite group, an analogue of barytolamprophyllite-2*M* with Mg predominant in *M*3 site and F predominant in *X* site and ‘linkage 1’ according to Sokolova (2006). It is named for the old name of the type locality, Liley (Dechen, 1861). The mineral and its name have been approved by the IMA Commission on New Minerals, Nomenclature and Classification (IMA no. 2011-021).

The type material is deposited in the collection of the Fersman Mineralogical Museum of the Russian Academy of Sciences, Moscow, Russia, registration number 4106/1.

2. Occurrence, general appearance and physical properties

Specimens with lileyite were collected in the Löhley quarry, Üdersdorf, near Daun, Eifel Mountains, Rhineland-Palatinate (Rheinland-Pfalz), Germany. Associated minerals are nepheline, leucite, augite, magnetite, fluorapatite, perovskite and götzenite. Götzeneite is partly substituted with an X-ray amorphous silicate of Ca and Ti with variable stoichiometry (white in Fig. 1a). Earlier, in the same assemblage at Löhley, another lamprophyllite-group mineral, schüllerite, $\text{Ba}_2\text{Na}(\text{Mn,Ca})(\text{Fe}^{3+},\text{Mg,Fe}^{2+})_2\text{Ti}_2(\text{Si}_2\text{O}_7)_2(\text{O,F})_4$, visually indistinguishable from lileyite, was discovered (Chukanov *et al.*, 2011). All these minerals occur in miarolitic cavities of alkaline basalt.

Lileyite is brown, translucent; streak is white. It forms platy crystals up to $0.1 \times 0.3 \times 0.5$ mm in size and their clusters up to 1 mm across on the walls of cavities in an alkaline basalt (Fig. 1). The main crystal form is {100}.

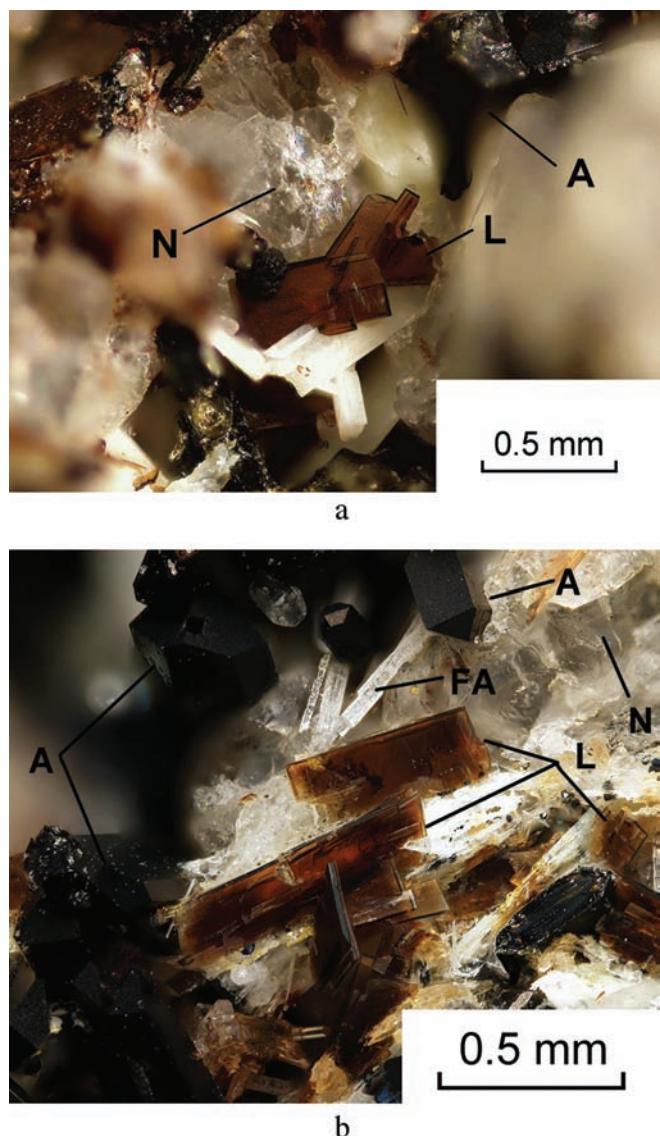

Fig. 1. Platy crystals of lileyite (L) with nepheline (N), augite (A) and fluorapatite (FA). Photo: F. Kruijen.

The new mineral is brittle, with Mohs hardness of 3–4 and perfect cleavage on (001). D_{calc} is 3.776 g/cm^3 . Lileyite is optically biaxial (+), $\alpha = 1.718(5)$, $\beta = 1.735(5)$, $\gamma = 1.755(5)$, $2V$ (meas.) = $75(15)^\circ$, $2V$ (calc.) = 86° . Dispersion is medium, $r > v$. Orientation: $X = a$; Y coincides with the elongation direction of crystals. Pleochroism is medium, Z (greyish-brown) > Y (light brown) > X (colourless).

The IR spectrum of lileyite (Fig. 2a) is different from those of other members of the lamprophyllite group (Fig. 2b–d). Absorption bands in the IR spectrum of lileyite and their assignments are (cm^{-1} ; s – strong band): 1032 s, 957 s, 901 s, 854 s (Si-O stretching vibrations), 680 (O-Si-O bending vibrations of Si_2O_7 groups), 578, 529 (Ti-O stretching vibrations of the TiO_5 polyhedra), 458 s,

vibrations of H-, B- or C-bearing groups) are absent in the IR spectrum.

3. Chemical data

Five electron-microprobe analyses were carried out using VEGA TS 5130MM SEM equipped with EDX analyser (INCA Si(Li) detector), at an operating voltage of 15.7 kV and a beam current of 0.5 nA. The program INCA Energy 200 was used for the analytical data calculation.

H_2O and CO_2 were not analysed because of the absence of bands corresponding to vibrations of O-H and C-O bonds in the IR spectrum. The contents of P, S, Al, V, Cr, Ni, Zn, Y, Zr, Ln, Th and U were found to be below detection limits. Analytical results are given in Table 1. The empirical formula of lileyite (based on 18 anions $\text{O}+\text{F}$ pfu) is:

$$\text{Ba}_{1.50}\text{Sr}_{0.19}\text{K}_{0.26}\text{Na}_{1.89}\text{Ca}_{0.36}\text{Mn}_{0.18}\text{Mg}_{0.99}\text{Fe}_{0.54}\text{Ti}_{2.01}\text{Nb}_{0.06}\text{Si}_{4.06}\text{O}_{16.23}\text{F}_{1.77}.$$

The simplified formula is $\text{Ba}_2(\text{Na,Fe,Ca})_3\text{MgTi}_2(\text{Si}_2\text{O}_7)_2\text{O}_2\text{F}_2$, taking into account the structural data (see below).

4. Crystal structure and X-ray powder diffraction data

Single-crystal X-ray studies of lileyite were carried out using an Xcalibur S CCD diffractometer; 3022 independent reflections ($|F| > 3\sigma$) were used for the structure determination. The crystal structure has been solved and refined using AREN and Jana programs (Andrianov, 1987; Petricek *et al.*, 2006). Mixed scattering curves were used for the composite cation sites. The details of data collection and structure refinement are given in Table 2. The results of the crystal structure refinement are given in Fig. 3 and 4 and Tables 3–6.

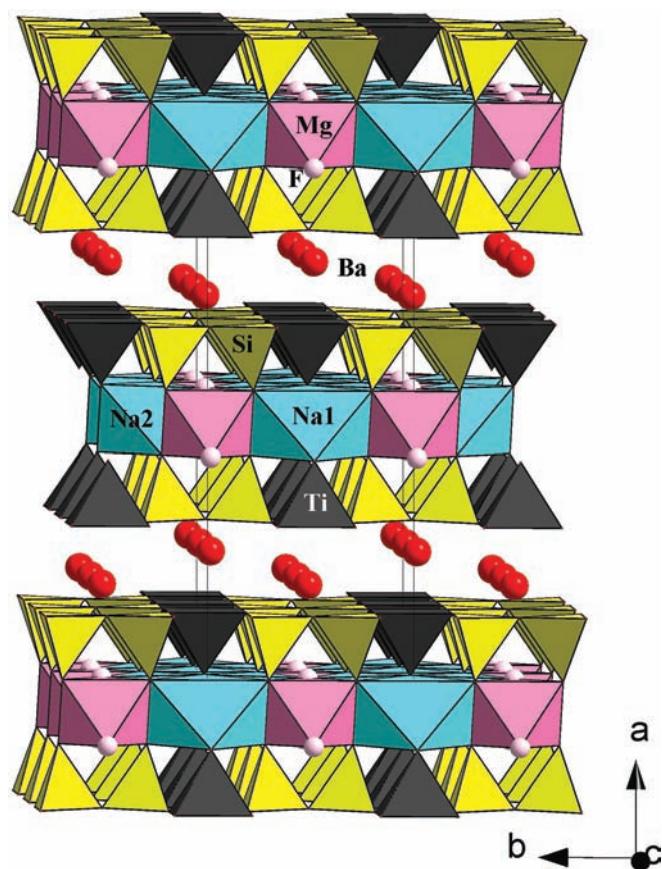

Fig. 3. The crystal structure of lileyite (general view).

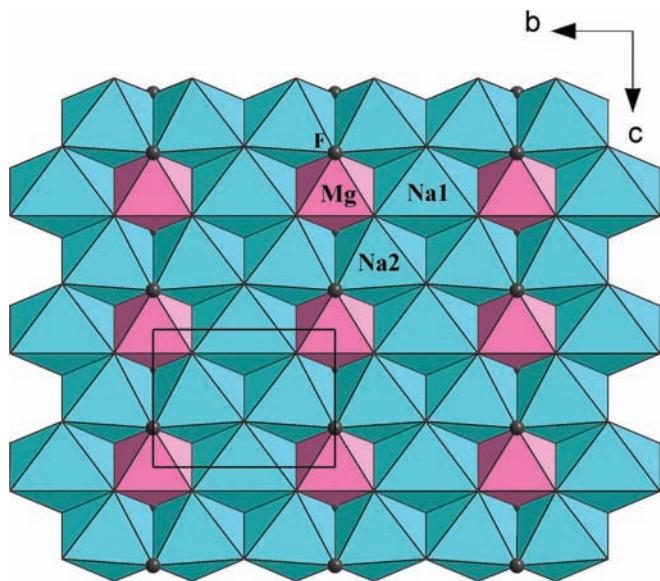

Fig. 4. The octahedral sheet in lileyite.

Lileyite is isostructural with 2M polytypes of lamprophyllite, barytolamprophyllite, ericssonite and ferroericssonite and is structurally related to nabalamprophyllite and schüllerite (Table 7).

A characteristic feature of the Na-dominant Na2 site is its ability to incorporate the bivalent cations Ca^{2+} , Fe^{2+} and Mn^{2+} (Peng *et al.*, 1984; Rastsvetaeva *et al.*, 1990, 1995). Large cations (Ba^{2+} , Sr^{2+} , K^+) are situated in the interlayer space. Fluorine is concentrated in the F site, as seen from bond valence calculations (Table 5). High valence sums for the Mg and Na2 sites with mixed occupancy (2.36 and 1.66, respectively) are consistent with the mean charge of cations in these sites (2.30 and 1.55, respectively).

The refined crystal-chemical formula of lileyite is $[\text{Ba}_{0.75}\text{K}_{0.15}\text{Sr}_{0.1}]_2[\text{Na}(\text{Na}_{0.45}\text{Ca}_{0.20}\text{Fe}^{2+}_{0.25}\text{Mn}_{0.10})_2(\text{Mg}_{0.80}\text{Fe}^{3+}_{0.10}\text{Ti}_{0.10})(\text{F}_{0.80}\text{O}_{0.20})_2][(\text{Ti}_{0.95}\text{Nb}_{0.05})_2(\text{Si}_2\text{O}_7)_2\text{O}_2]$, where interlayer contents, O sheet and H sheet are given in square brackets.

The X-ray powder diffraction data for lileyite (Table 8) were collected with a STOE IPDS II single-crystal diffractometer equipped with an image plate detector (MoK α radiation; the distance between sample and detector was 200 mm) using the Gandolfi method. They are well indexed in the monoclinic unit cell found by single-crystal studies; the unit-cell parameters refined from the powder data are: $a = 19.94(2)$, $b = 7.094(7)$, $c = 5.404(6)$ Å, $\beta = 96.23(8)$ °, $V = 760(2)$ Å³.

5. Discussion

Members of the lamprophyllite-barytolamprophyllite iso-morphic series are typical accessory minerals of peralkaline (agpaitic) rocks and pegmatites. The content of MgO

in these minerals does not exceed 1.5 wt% (Zaitsev & Kogarko, 2002; Azarova, 2004).

Alkaline basalts of the Eifel volcanic area contain basanitic (magnesian) clinopyroxene and, routinely, olivine as main rock-forming components (Wörner & Wright, 1984). These rocks are much more enriched in Mg than the majority of agpaitic rocks that typically host titanium lamprophyllite-group minerals. This seems to be the main cause of magnesium enrichment of lileyite. The incorporation of bivalent cations in the Ti-dominant *M3* site of lamprophyllite and barytolamprophyllite from peralkaline rocks is hindered also by charge-balance conditions because of high contents of univalent alkali metals in these minerals.

Lileyite and all associated primary minerals practically do not contain hydrogen. This is an indication that a high-

Table 7. Comparative data for monoclinic titanium lamprophyllite-group minerals.

Mineral	Lileyite	Barytolamprophyllite	Lamprophyllite	Nabalamprophyllite	Schüllerite
Simplified formula	$\text{Ba}_2(\text{Na},\text{Fe},\text{Ca})_3$ $\text{MgTi}_2(\text{Si}_2\text{O}_7)_2\text{O}_2\text{F}_2$	$\text{Ba}_2(\text{Na},\text{Fe},\text{Mn})_3\text{Ti}_3$ $(\text{Si}_2\text{O}_7)_2\text{O}_2(\text{O},\text{OH},\text{F})_2$	$\text{Sr}_2(\text{Na},\text{Fe},\text{Mn})_3\text{Ti}_3$ $(\text{Si}_2\text{O}_7)_2\text{O}_2(\text{O},\text{OH},\text{F})_2$	$\text{Ba}(\text{Na},\text{Ba})\text{Na}_3$ $\text{Ti}_3(\text{Si}_2\text{O}_7)_2\text{O}_2(\text{OH})_2$	$\text{Ba}_2\text{Na}(\text{Mn},\text{Ca})(\text{Fe}^{3+},\text{Mg},\text{Fe}^{2+})_2$ $\text{Ti}_2(\text{Si}_2\text{O}_7)_2(\text{O},\text{F})_4$

3	1.191	3, 3	1.192, 1.190	950, 91-4
2	1.184	3, 2	1.187, 1.183	10.2.3, 060

Note: ^aCalculated with single-crystal unit-cell parameters. For calculated X-ray data, only reflections with intensities ≥ 1 are given.

temperature, pneumatolytic origin of lileyite is more probable than a hydrothermal one.
