Abstract

The new mineral pansnerite, ideally $K_3Na_3Fe_6^{3+}(AsO_4)_8$, was found in the Arsenatnaya fumarole at the Second scoria cone of the Northern Breakthrough of the Great Tolbachik Fissure Eruption, Tolbachik volcano, Kamchatka, Russia. It is associated with aphthitalite, hematite, sanidine, badalovite, khrenovite, achyrophanite, arsenatrotitanite, ozerovaite, tilasite, calciojohillerite, johillerite, nickenichite, svabite, katiarsite, yurmarinite, anhydrite, rutile, cassiterite and pseudobrookite. Pansnerite forms tabular to lamellar (flattened on {010}), usually pseudohexagonal crystals up to 0.2 mm × 0.7 mm × 1 mm and crystal clusters up to 2 mm across. It is transparent to translucent, light green, pale greenish, yellowish-greenish or yellowish, with vitreous lustre. The mineral is brittle, with perfect {010} cleavage. The Mohs' hardness is ca 3. D_{calc} is 3.596 g cm⁻³. Pansnerite is optically biaxial (-), $\alpha = 1.702(4)$, $\beta = 1.713(4)$, $\gamma = 1.717(4)$, $2V_{meas} = 45(10)^{\circ}$ and $2V_{calc} = 62^{\circ}$. Chemical composition (holotype, wt.%, electron microprobe data) is: Na₂O 6.39, K₂O 8.52, CaO 0.08, MgO 0.08, MnO 0.02, NiO 0.02, CuO 1.35, ZnO 0.34, Al₂O₃ 7.35, Cr₂O₃ 0.04, Fe₂O₃ 16.72, SiO₂ 0.16, P₂O₅ 0.22, V₂O₅ 0.09, As₂O₅ 57.76, SO₃ 0.04, total 99.20. The empirical formula based on 32 O apfu is $K_{2.86}Na_{3.26}Ca_{0.02}(Fe_{3.31}^{3+}Al_{2.28}Cu_{0.27}Zn_{0.07}Mg_{0.03}Cr_{0.01})_{\Sigma 5.97}(As_{7.95}P_{0.05}Si_{0.04}V_{0.02}S_{0.01})_{\Sigma 8.06}O_{32}$. Pansnerite is orthorhombic, *Cmce*, a = 10.7372(3), b = 20.8367(8), c = 6.47335(15) Å, V = 1448.27(7) Å³ and Z = 2. The strongest reflections of the X-ray powder diffraction pattern [d, Å(I)(hkl)] are: 10.49(100)(020), 5.380(88)(111), 4.793(65)(220), 3.105(46)(311, 002), 3.079(32)) (112, 061), 2.932(35)(260), 2.783(65)(202) and 2.694(52)(400, 222). The crystal structure was solved from single-crystal X-ray diffraction data, $R_1 = 2.82\%$. The structure is based on heteropolyhedral layers formed by MO_6 octahedra ($M = Fe^{3+}$ and Al) sharing common vertices and connected by AsO₄ tetrahedra. Na⁺ and K⁺ cations are located in the interlayer space. The mineral is named in honour of the German-Russian mineralogist and geographer Lavrentiy Ivanovich Pansner (1777-1851). Pansnerite forms a solid-solution series with the isotypic mineral ozerovaite, ideally KNa2Al3(AsO4)4.

Keywords: pansnerite, new mineral, potassium sodium iron arsenate, ozerovaite, crystal structure, fumarole sublimate, Tolbachik volcano, Kamchatka

(Received 25 April 2019; accepted 23 July 2019; Accepted Manuscript published online: 30 July 2019; Associate Editor: Michael Rumsey)

Introduction

The present article continues the series of papers devoted to descriptions of new arsenate minerals from the Arsenatnaya fumarole at the Second scoria cone of the Northern Breakthrough of the Great Tolbachik Fissure Eruption (1975–1976), Tolbachik volcano, Kamchatka Peninsula, Far-Eastern Region, Russia (55°41′N 160° 14′E, 1200 m asl). Fifteen new arsenates from this locality were characterised in the previous articles of the series: yurmarinite Na₇(Fe³⁺,Mg,Cu)₄(AsO₄)₆ (Pekov *et al.*, 2014*a*), two polymorphs of Cu₄O(AsO₄)₂, ericlaxmanite and kozyrevskite (Pekov *et al.*,

2014*b*), popovite $Cu_5O_2(AsO_4)_2$ (Pekov *et al.*, 2015*a*), structurally related shchurovskyite $K_2CaCu_6O_2(AsO_4)_4$ and dmisokolovite $K_3Cu_5AlO_2(AsO_4)_4$ (Pekov *et al.*, 2015*b*), katiarsite KTiO(AsO_4) (Pekov *et al.*, 2016*a*), melanarsite $K_3Cu_7Fe^{3+}O_4(AsO_4)_4$ (Pekov *et al.*, 2016*b*), pharmazincite KZnASO_4 (Pekov *et al.*, 2017*a*), arsenowagnerite Mg₂(AsO_4)F (Pekov *et al.*, 2018*b*), arsenatrotitanite NaTiO(AsO_4) (Pekov *et al.*, 2019*a*), the two isostructural minerals edtollite $K_2NaCu_5Fe^{3+}O_2(AsO_4)_4$ and alumoedtollite $K_2NaCu_5AlO_2(AsO_4)_4$ (Pekov *et al.*, 2019*b*), anatolyite Na₆(Ca, Na)(Mg₅Fe^{3+})_3Al(AsO_4)_6 (Pekov *et al.*, 2019*c*) and zubkovaite Ca₃Cu₃(AsO_4)₄ (Pekov *et al.*, 2019*d*).

In this paper the new mineral pansnerite (Cyrillic: панснерит), ideally $K_3Na_3Fe_6^{3+}(AsO_4)_8$, is described. It is named in honour of Lavrentiy Ivanovich Pansner (1777–1851), the German–Russian mineralogist and geographer (his initial German name was Johann Heinrich Lorenz von Pansner, or, in another spelling, Panzner). Dr. Pansner, a specialist in studies of physical

Scanning electron microscopy (secondary electron) images.

properties of minerals, became the first Ordinary Professor of Mineralogy at St Petersburg University (1819–1822). He was one of the founders of the Russian Mineralogical Society (1817) and its first Director (1817–1824).

Both new mineral and its name have been approved by the IMA Commission on New Minerals, Nomenclature and Classification (IMA–CNMNC), IMA2016–103 (Pekov *et al.*, 2017*b*). Parts of the holotype specimen (#5402 - see later) are deposited in the systematic collection of the Fersman Mineralogical Museum of the Russian Academy of Sciences, Moscow, with the catalogue numbers 95899 and 95911.

In terms of crystal structure, pansnerite is isotypic to ozerovaite, ideally $KNa_2Al_3(AsO_4)_4$, a mineral recently discovered in another fumarole located at the same Second scoria cone of the Northern Breakthrough of the Great Tolbachik Fissure Eruption (Shablinskii *et al.*, 2019). We found a novel, Fe-rich variety of ozerovaite in the Arsenatnaya fumarole and detected the solidsolution series between this mineral and pansnerite. These data have been included in the present paper.

Occurrence, mineral associations and morphology

The Second scoria cone is a monogenetic volcano formed in 1975 as a result of eruptive activity of the Northern Breakthrough of the

Great Tolbachik Fissure Eruption. It is located 18 km SSW of the Ploskiy Tolbachik volcano (Fedotov and Markhinin, 1983). The Arsenatnaya fumarole belongs to the main fumarole field situated at the summit of the Second scoria cone and is still active. The general data on Arsenatnaya and sublimate mineralisation produced by this fumarole have been reported by Pekov *et al.* (2014*a*, 2018*a*).

The material from which the holotype of pansnerite (sample #5402) originates was collected by us in July 2016 from a pocket \sim 1.5 m below the current surface at the northern part of the Arsenatnaya fumarole. The temperature (measured using a chromel-alumel thermocouple) in this pocket at the time of collecting was 430°C. Pansnerite occurs in polymineralic incrustations on basalt scoria altered by fumarolic gas. The new mineral forms tabular to lamellar, usually pseudo-hexagonal crystals flattened on {010}. They are well-shaped or, more commonly, crude and cavernous (Figs 1a,b), typically up to 0.3 mm across, rarely up to $0.2 \text{ mm} \times 0.7 \text{ mm} \times 1 \text{ mm}$. Crystals are usually combined in clusters (Figs 1b and 2) up to 2 mm or open-work aggregates up to 1 cm across. Minerals associated with pansnerite are aphthitalite, hematite, badalovite, calciojohillerite, khrenovite, achyrophanite, ozerovaite, arsenatrotitanite, johillerite, nickenichite, svabite, tilasite, As-bearing sanidine, anhydrite, rutile, cassiterite, and pseudobrookite. The pansnerite sample richest in Al (with $Fe \ge Al$, sample #5402d) was also from there.

Fig. 2. Yellowish-greenish aggregate of pansnerite (holotype specimen with working number 5402 by I.V. Pekov) partially overgrown by whitish aphthitalite with minor amounts of iron-black hematite and brownish-yellow badalovite. Width of photograph: 1.2 mm. Photo: I.V. Pekov and A.V. Kasatkin.

An iron-rich variety of ozerovaite (sample #5443) was found in the same assemblage and is similar to pansnerite in morphology and size of crystals and aggregates (Fig. 1*d*) but not in colour. During our fieldwork in July 2018, an Al-poor variety of pansnerite (samples #6514 and #6515) was found in another pocket, in a slightly different mineral association. It occurs in vesicles and cracks of basalt scoria replaced by rusk-like aggregates of potassic feldspar as the result of alteration by fumarolic gas. In this pocket, pansnerite forms as tabular or lamellar pseudo-hexagonal crystals flattened on $\{010\}$ (Fig. 1c) up to 0.2 mm across associated with As-bearing potassic feldspar, katiarsite (including its Sn-rich variety), yurmarinite, achyrophanite, badalovite, khrenovite, arsenatrotitanite, tilasite, aphthitalite, anhydrite and hematite.

The main form of crystals of both pansnerite and ozerovaite is the pinacoid {010} (Fig. 1); lateral faces could not be indexed.

We consider sample #5402 as the holotype of pansnerite: the proposal IMA2016-103 approved by the IMA-CNMNC (Pekov *et al.*, 2017*b*) was based on the studies of only this specimen. Samples #5402d, #6514 and #6515, also described in the present paper, were found and studied later and are not the type specimens of pansnerite.

We believe that pansnerite and ozerovaite were deposited from hot gas as sublimates or formed as a result of the interaction between fumarolic gas and basalt scoria at the temperatures not lower than 430–450°C.

Physical properties and optical characteristics

Pansnerite is transparent in small individuals and translucent in aggregates. Its colour is pale greenish to light green, yellowish-greenish or yellowish (ozerovaite associated with holotype pansnerite differs from it in colour being pale reddish to yellowish-pinkish). Streak is white. Lustre is vitreous. The new mineral is brittle. Cleavage is (010) perfect. The fracture is stepped. The Mohs' hardness is \sim 3. Density calculated using the empirical formula is 3.596 g cm⁻³.

*[3] Holotype specimen: average data for six analyses from three crystals, ranges are in parentheses; [4] crystal extracted from the holotype specimen and used for structure determination. **Probe standards used at Moscow State University (MSU) and Fersman Mineralogical Museum of the Russian Academy of Sciences (FMM), respectively. ***Total also includes 0.02 wt.% TiO₂ (probe standards for MSU/FMM = KTiOPO₄/ilmenite).

Analyses are ordered by decreasing Fe:Al ratio; sources: [1-7] our data; [8] Shablinskii et al. (2019); - = below detection limit

Optical properties were determined for holotype pansnerite. It is optically biaxial (-), $\alpha = 1.702(4)$, $\beta = 1.713(4)$ and $\gamma = 1.717(4)$ (589 nm). $2V_{\text{meas}} = 45(10)^{\circ}$ (estimated by the curve of the conoscopic figures on the sections perpendicular to optical axis), $2V_{\text{calc}} = 62^{\circ}$. Dispersion of optical axes is very strong, r > v and orientation is: $X = \mathbf{b}$; Y and Z lie in the **ac** plane. In planepolarised light, pansnerite is non-pleochroic, colourless in thin grains and slightly greenish in thicker grains. With crossed polarisers, pasnerite demonstrates pink and blue anomalous interference colours.

Raman spectroscopy

The Raman spectrum of the holotype pansnerite (Fig. 3) was obtained using an EnSpectr R532 spectrometer with a green laser (532 nm) at room temperature. The output power of the laser beam was ~16 mW. The spectrum was processed using the *EnSpectr* expert mode program in the range 4000 to 100 cm^{-1} with a resolution of 6 cm⁻¹. The diameter of the focal spot on the sample was ~10 µm. The spectrum was obtained for a randomly oriented crystal.

*For the calculated X-ray diffraction pattern only reflections with intensities ≥1 are given; **for the unit-cell parameters calculated from single-crystal data. The strongest lines are given in bold.

The bands in the region 700–1000 cm⁻¹ correspond to $As^{5+}-O$ stretching vibrations of distorted (see below) tetrahedral AsO₄ groups. The band at 549 cm⁻¹ can be assigned to Al–O stretching vibrations and the band at 451 cm⁻¹ to Fe³⁺–O stretching vibrations. Bands with frequencies lower than 400 cm⁻¹ correspond to $As^{5+}-O$ bending vibrations of AsO_4^{3-} anions, Fe³⁺–O and Al–O stretching vibrations and lattice modes. The absence of bands with frequencies higher than 1000 cm⁻¹ indicates the absence of groups with O–H, C–H, C–O, N–H, N–O and B–O bonds in pansnerite.

Chemical composition

The chemical composition of pansnerite and Fe-rich ozerovaite was studied by electron microprobe in two laboratories. In the Laboratory of Analytical Techniques of High Spatial Resolution at the Department of Petrology of Moscow State University, the chemical compositions of the minerals were determined using a Jeol JSM-6480LV scanning electron microscope equipped with an INCA-Wave 500 wavelength-dispersive spectrometer. In the Fersman Mineralogical Museum of the Russian Academy of

*Single crystal extracted from the holotype specimen and used for structure determination.

Samples are ordered by decreasing Fe:Al ratio. For chemical composition of the samples see Table 1. 'apfu' = atoms per formula unit.

Sciences, the samples were studied using a Jeol 733 electron microprobe instrument. In both laboratories the analyses were carried out using wavelength-dispersive spectroscopy mode, with an acceleration voltage of 20 kV, a beam current of 20 nA and a beam diameter of 3 μ m.

The chemical composition and the standards used for pansnerite and ozerovaite are given in Table 1. Contents of other elements with atomic numbers higher than carbon are below detection limits. Ratios of major octahedrally coordinated cations, Fe^{3+} -Al-(Cu²⁺ + Zn + Mg) are shown in Fig. 4.

The empirical formula of holotype pansnerite (No. 3 in Table 1) calculated on the basis of 32 O atoms per formula unit is: $K_{2.86}Na_{3.26}Ca_{0.02}(Fe_{3,31}^{3+}Al_{2.28}Cu_{0.27}Zn_{0.07}Mg_{0.03}Cr_{0.01})_{\Sigma 5.97}(As_{7.95}P_{0.05}Si_{0.04}V_{0.02}S_{0.01})_{\Sigma 8.06}O_{32}$. The idealised, end-member formula of the new mineral is $K_3Na_3Fe_6^{3+}(AsO_4)_8$ which requires Na_2O 5.69, K_2O 8.65, Fe_2O_3 29.34, As_2O_5 56.32, total 100.00 wt.%.

X-ray crystallography and crystal-structure determination details

Powder X-ray diffraction (XRD) data of pansnerite (Table 2) were collected with a Rigaku R-AXIS Rapid II diffractometer equipped with a cylindrical image plate detector (radius = 127.4 mm) using Debye–Scherrer geometry, CoK α radiation (rotating anode with VariMAX microfocus optics), 40 kV, 15 mA and an exposure time of 10 min. Angular resolution of the detector is 0.045°20 (pixel size 0.1 mm). The data were integrated using the software package *Osc2Tab* (Britvin *et al.*, 2017). Single-crystal XRD studies of pansnerite and Fe-rich ozerovaite were carried out using an Xcalibur S diffractometer equipped with a CCD detector (MoK α radiation). The unit-cell parameters of both minerals are reported in Table 3.

The crystal structure of pansnerite was studied using a single crystal extracted from the holotype specimen. The chemical composition of this crystal is given in Table 1 (No. 4) and the empirical formula corresponding to this analysis is $K_{2.93}Na_{3.07}Ca_{0.02}(Fe_{2.94}^{3+}Al_{2.78}Cu_{0.27}Zn_{0.07}Cr_{0.03}Ni_{0.01})_{\Sigma 6.10}(As_{7.91}P_{0.05}Si_{0.03}V_{0.02})_{\Sigma 8.01}O_{32}$. A full sphere of three-dimensional data was collected. Data reduction was performed using *CrysAlisPro* Version 1.171.37.35 (Agilent Technologies, 2014). The data were corrected for Lorentz, polarisation and absorption effects. The structure was solved by direct methods and refined with the use of the *SHELX-97* software package (Sheldrick, 2008) to $R_1 = 0.0282$ for 939 unique reflections with $I > 2\sigma(I)$. The crystal data, data collection information and structure refinement details are given in Table 4, atom

coordinates, equivalent and anisotropic displacement parameters, site occupancies and multiplicities in Table 5, selected interatomic distances in Table 6 and bond-valence calculations in Table 7. The crystallographic information file has been deposited with the Principal Editor of *Mineralogical Magazine* and is available as Supplementary material (see below).

Discussion

Crystal structure

The crystal structure of pansnerite (Fig. 5) is based on heteropolyhedral layers parallel to {010}. They are formed by M(1,2)O₆ ($M = \text{Fe}^{3+}$ and Al) octahedra sharing common vertices and

*Admixed constituents (see No. 4 in Table 1) were ignored during refinement. **Constraints were applied to the site occupancies of Na⁺ and K⁺ cations to achieve electroneutrality; distribution of Na and K could be slightly different in case Na is admixed in the K(2) site and K substitutes Na in Na(1); interatomic distances (Table 6) show that such substitutions can be only minor. ***U_{iso}.

connected by AsO₄ tetrahedra via common vertices and edges. These layers constitute a structural unit in ozerovaite, ideally KNa₂Al₃(AsO₄)₄ (Shablinskii et al., 2019), and several synthetic arsenates and phosphates (with $M = Cr^{3+}$, Fe³⁺ or Al) isotypic with these two minerals, namely $K_3Cr_3^{3+}(AsO_4)_4$ (Friaa *et al.*, 2003), $K_3Fe_3^{3+}(AsO_4)_4$ (Ouerfelli *et al.*, 2005), $K_3Cr_3^{3+}(PO_4)_4$ (Kouass and Boughzala, 2006), Na_{2.08}K_{0.92}Al₃(AsO₄)₄ (Ben Yahia et al., 2010), $K_{1.8}Sr_{0.6}Al_3(AsO_4)_4$ (Haj Abdallah and 2012), $Na_{1.67}K_{1.33}Al_3(AsO_4)_4$ (Bouhassine Haddad, and Boughzala, 2014) and Na_{2,77}K_{1,52}Fe³⁺_{2,57}(AsO₄)₄ (Ouerfelli *et al.*, 2015). The arsenate Na_{2.08}K_{0.92}Al₃(AsO₄)₄ (Ben Yahia et al., 2010) is chemically similar to end-member ozerovaite. All these compounds adopt the same space group Cmce (no. 64, formerly designated as Cmca) and in terms of unit-cell parameters they are close to one another and to pansnerite: see an overview given by Shablinskii et al. (2019). In the crystal structure of $K_3Fe_3^{3+}(PO_4)_4 \cdot H_2O$ (with similar unit cell and space group Pnna), the layers formed by FeO₆ octahedra and PO₄ tetrahedra are topologically the same (Lii, 1995). The difference between

this phosphate and above-mentioned compounds is the presence of H₂O molecules in the interlayer space of the former and different arrangements of the neighbouring layers (Friaa *et al.*, 2003). The same topology of heteropolyhedral layers was also found in Na₃Fe₃³⁺(PO₄)₄ (Lajmi *et al.*, 2002) and in KFe₃(AsO₄)₂(HAsO₄)₂ (Schwendtner and Kolitsch, 2007), which have metrically similar monoclinic unit cells with $\beta = 91.8^{\circ}$ and $\beta = 100.42^{\circ}$ respectively and space group *C*2/*c*.

All alkali-cation sites in pansnerite are only partially occupied. This is typical for the synthetic compounds belonging to this structure family (see references in previous paragraph). The Na(1) and Na(2) sites occur in the interlayer space and are coordinated by oxygen atoms belonging to two neighbouring layers. The Na(1), with an occupancy of 56%, centres a seven-fold coordination polyhedron whereas the additional Na(2) site, with 12% occupancy, is surrounded by four oxygen atoms. Na(1) and Na(2), as well as two neighbouring Na(2) sites, cannot be occupied simultaneously due to their close location (Fig. 5): the Na(1)-Na(2) distance is 0.90 Å and the Na(2)-Na(2) one is 1.60 Å. The K(1) site, filled by K (32%), is also located in the interlayer and is the centre of an eight-fold polyhedron. This site could not be occupied fully due to a short K(1)-K(1) distance: 1.50 Å (Fig. 5). An additional, low-occupancy (6%) K(2) site, found from the difference-Fourier map, is situated in a hole in the heteropolyhedral layer and has nine-fold coordination. Bond lengths in Na- and K-centred polyhedra (Table 6) indicate that the K(2) site could contain some Na whereas Na(1) could contain minor K. There would be no straightforward way to address them in the refinement because of the low partial occupancies of the sites. The highest peak on the difference-Fourier map $(1.30 \text{ } e^{-}/\text{Å}^{3})$ was also not included in the structure model. It could be assigned to another additional Na site with very low occupancy [this peak has the following coordinates: x = 0.0, y = 0.1272 and z = 0.0616and is located 0.72 Å from Na(1)].

Interatomic distances in the MO_6 octahedra (Table 6) and the presence of the band at 451 cm⁻¹ in the Raman spectrum (Fig. 3) show that iron in pansnerite is trivalent. This is in good agreement with: (1) the stoichiometry of the mineral; (2) the fact that all above-mentioned synthetic arsenates and phosphates structurally related to pansnerite contain only trivalent octahedrally coordinated cations (Al, Cr³⁺ and Fe³⁺); and (3) the strongly oxidising conditions of mineral formation in the Arsenatnaya fumarole (Pekov *et al.*, 2014*a*). The refined number of electrons (e_{ref}) in

The parameters were taken from Gagné and Hawthorne (2015). Site occupancy factors were taken into account. *The value could be slightly increased taking into account a possible K admixture.

Fig. 5. The crystal structure of pansnerite. The unit cell is outlined.

the *M* sites is 20.1 e^- that is close to the value calculated from the formula based on the electron microprobe data: 20.3 e^- .

Pansnerite-ozerovaite solid-solution series

Pansnerite and ozerovaite, arsenates with the idealised formulae $K_3Na_3Fe_6^{3+}(AsO_4)_8$ and $KNa_2Al_3(AsO_4)_4$ [or $K_2Na_4Al_6(AsO_4)_8$, with Z = 2], respectively, are isotypic. The main difference between them is the dominance of either Fe³⁺ or Al. As our data show, these minerals form a solid-solution series in which two significant gaps are observed (Fig. 4). This series is, thus, subdivided into three separated parts: (1) Fe-poor ozerovaite [the holotype ozerovaite described by Shablinskii *et al.* (2019)]; (2) Al-poor pansnerite (sample #6514 and 6515); and (3) varieties of both mineral species with compositions near the point with equal amounts of Al and Fe (sample #5402 and 5402d). The K:Na ratio is more invariant and closer to 1.0 in Fe-dominant samples (pansnerite part of the series)

compared with Al-dominant samples (ozerovaite part of the series) in which the K:Na ratio varies significantly and is relatively higher in Na (Table 1). The unit-cell parameters a and c and the unit-cell volume gradually decrease in the pansnerite–ozerovaite series with decreasing Fe:Al ratio (Table 3).

The isotypism of pansnerite and ozerovaite and the existence of numerous synthetic compounds with analogous structure make it likely that the pansnerite-ozerovaite solid-solution series is, in fact, complete.

Acknowledgements. We thank referees Anthony R. Kampf, Peter Leverett and Uwe Kolitsch and Associate Editor Mike Rumsey for valuable comments. This study was supported by the Russian Foundation for Basic Research, grant no. 17-05-00179. The technical support by the SPbSU X-Ray Diffraction Resource Center in the powder XRD study is acknowledged.
